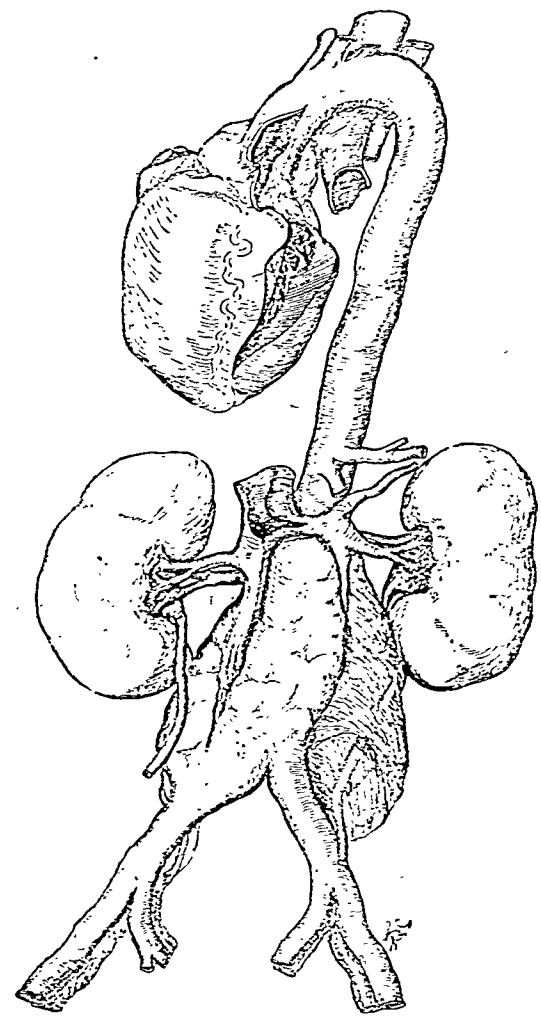
An engineer, aged 35, was admitted to the General Hospital, Birmingham, on August 21st, 1928, giving the following history. In 1912, at the age of 18, having previously been in good health, he was treated for iritis, which, he stated, followed a blow on the eye. The iritis cleared up rapidly under treatment, the nature of which is not known. Two years later he was admitted to this hospital, under the late Dr. Saundby, complaining of swelling of both legs, the onset being sudden and accompanied by pain in the legs. A diagnosis of bilateral femoral thrombosis was made, but no local or general cause was discovered. There was no clinical evidence of syphilis, but the Wassermann reaction was not determined. After some weeks the legs ulcerated and the oedema diminished. During the ensuing six years he had several transient recurrences of oedema, but no pain occurred with these attacks. In 1918 he began to have difficulty in walking of the type associated with intermittent claudication. This symptom persisted to a variable extent for the rest of his life. In 1920 large veins appeared over the abdomen and the ulcers healed. A year later he was readmitted, under Dr. Stanley Barnes, complaining of severe aching pains in the lower part of the back, and he was found to have the large superficial venous collateral circulation typical of obstruction of the inferior vena cava. He was tender over the lower lumbar spines, and had a bilateral extensor plantar response. The Wassermann reaction was negative. Thrombosis of the inferior vena cava, with a light degree of myelitis, was diagnosed, the myelitis being thought to be due to a local impoverishment of the blood supply secondary to the thrombosis. His pain disappeared under electrical treatment, and he returned to work. He remained free from pain until 1927,



when he had a recurrence of symptoms, of a short duration, similar in every respect to those of 1921.

Four weeks before admission he had a similar recurrence of pain of very great severity, especially located in the left side of the abdomen. The pain caused complete insomnia, and after two weeks of acute distress a swelling appeared in the left groin, followed by numbness and uselessness of the left leg. Violent nocturnal stabbing pain arose, shooting down the left thigh.

On examination (August 21st, 1928) extensive symmetrical pigmented papery scars were found on both legs. Large tortuous veins coursed over the abdomen from the groins to the substernal notch and the axillae, the blood flow in every case being upwards. A diffuse, solid, tender swelling occupied the left groin, and the left leg was flexed at the hip, any attempt at extension causing violent pain. No pulsation could be detected in the arteries of the lower extremities except a feeble intermittent pulse in the left posterior tibial. There was no oedema of the legs. The radial pulses were regular, rapid (120), and of high tension, the blood pressure being 160 systolic and 105 diastolic. The abdomen was

uniformly distended and tympanitic, prohibiting palpation of its contents. There were now no signs of myelitis.

Thirty-six hours after admission he had *an attack of agonizing* pain shooting down the left leg, the abdominal distension increased, and vomiting and collapse occurred. From that time until death the pain recurred at intervals, necessitating the frequent use of morphine, and the radial pulses became very thin and rapid, being imperceptible at times. The swelling in the groin gradually diminished, and the left common femoral pulse was felt for a few hours on the third day. On the fourth day a large mass became visible and palpable in the left side of the abdomen, extending from the costal *margin* to the iliac crest, and from the left kidney region to within three *inches* of the umbilicus, and exhibiting pulsation of an expansile character. A soft systolic murmur was audible over the swelling. An *x-ray examination* at this time showed no sign of *abdominal* aneurysm, but a lateral view was impossible. The swelling increased steadily in size until it filled the greater part of the left side of the abdomen and the *meteorism subsided*. A spreading *discoloration* of the skin of the left loin and groin *appeared*. The day before death, which occurred a week after admission, a collection of fluid was detected in the left pleural cavity, but it was not tapped, as the patient was dying.

At the necropsy he was found to *have*, at the bifurcation of the aorta, a large saccular aneurysm, which had eroded the bodies of the fourth and fifth lumbar vertebrae to within half an *inch* of the *spinal canal*. The posterior wall of the aneurysmal *cavity* was formed by *this eroded* surface, and on the left side the junction of the sac with the lip of the *vertebral* hollow had broken down, allowing the escape of blood into the *retroperitoneal* tissues, where a huge *haematoma* was formed. The *swelling* in the left groin was due to this extravasation of blood tracking down the psoas muscle. The inferior vena cava was indistinguishable two *inches* below the renal veins, where it became *stretched out over* the sac of the aneurysm as a fibrous band. The femoral and *iliac* veins were represented by thick fibrous cords partly recanalized by *small* vessels running outwards near the *bifurcation* of the *aorta, apparently* into the lumbar veins. The arteries of the *legs* were *patent*, but a loose mass of laminated clot was partly blocking the openings from the aneurysm *into the common* iliac arteries. The heart was normal, and the aorta showed *no aortitis or atheroma*. The other organs were examined and found to be healthy. No signs of syphilitic infection were found. In the left pleural cavity a quantity of *blood* was discovered that had tracked up through the crura of the *diaphragm*.

Comment.

The *condition revealed* at the necropsy explains the course of this distinctly puzzling case.

There can be little doubt that, fourteen years before death, *a developing* aneurysm of the abdominal aorta caused thrombosis of the inferior vena cava, with its subsequent train of symptoms, and, slowly eroding the *vertebrae*, gave rise to the attacks of lumbar pain. The myelitis and intermittent claudication must have been due to a *deficient* arterial supply from the vessels partly obstructed at their origins by the mass of *clot in the sac*. The sac then broke away from the vertebrae posteriorly, allowing leakage into the left *psoas sheath*. More extensive *tearing* preceding death caused the formation of a large false aneurysm, rendering the condition obvious for the first time.

Apart from the rarity of this *condition several points* of interest arise. In the first place the etiology of the aneurysm is difficult to determine. With the possible exception of the iritis no evidence, clinical or pathological, of syphilitic infection was present. The aneurysm itself, however, was of the saccular variety, and, in the absence of any possibility of *occupational trauma*, must be considered to be syphilitic. The onset before the age of 20 implies that the infection was congenital or *neo-natal* in *origin*, although no stigmata of congenital syphilis were *present*. It was unfortunate that the grave condition of the patient prohibited the *taking* of a second Wassermann *reaction*.

The slow *progress*, fourteen years, and the absence of lumbar pain, except for two short periods, *are remarkable* when the *degree* of bone involvement is considered.

Lastly the absence of any *sign* of erosion on an antero-posterior *radiograph* is noteworthy, and *suggests* the desirability of a lateral view in cases of "backache" of obscure causation.

I have to thank Dr. Stanley Barnes for permission to publish these notes.

OCCUPATIONAL PRESSURE NEURITIS OF THE DEEP PALMAR BRANCH OF THE ULNAR NERVE.

BY

WILFRED HARRIS, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR NERVOUS DISEASES, MAIDA VALE.

PRESSURE paralysis of the whole ulnar nerve is not uncommon, either as the result of pressure of the head of the humerus in the axilla following dislocation of the shoulder, or as the result of pressure upon the nerve during sleep, or under prolonged anaesthesia, from the forearm being kept acutely flexed at the elbow, or resting against the sharp edge or back of a chair. It is rare for the nerve to suffer from the results of pressure in the forearm itself, though a certain degree of neuritis may accompany Volkmann's ischaemic myositis as the result of too tight bandaging of the limb. As the result of prolonged pressure in the palm of the hand upon the median nerve branches I have seen numbness and partial anaesthesia of the three middle digits; and prolonged repeated pressure, as in floor-scrubbers, or in gardeners, from the use of the trowel, may cause atrophy of the thenar eminence from an occupation neuritis of the branches of the median to the opponens and abductor pollicis.

Until recently I have never seen a pressure neuritis of the deep palmar branch of the ulnar, nor do I know of any description of such condition, but two cases which I saw within a week were so clearly limited to this nerve branch that possibly its apparent rarity may be due to want of recognition. Both cases were identical in the type of paralysis and in the complete absence of complaint of pain or of anaesthesia. The first patient was a bootmaker, whose constant use of one weapon, a knife, in cutting out the leather, had raised horny callosities of the skin of the palm on the inner side of the hypothenar eminence. The other was a motor-cyclist, whose hobby was long week-end rides on a high-powered *machine*, and whose *right* hand had suffered from his trick of gripping the handle-bar and controls too tightly. In each case the paralysis was limited to abduction and adduction of the three outer fingers, and adduction of the thumb. There was no wasting of either the thenar or hypothenar eminence, and no weakness of abduction or opposition of the thumb and little finger, but great difficulty was experienced in writing and in picking up a small coin or pin. Neither the first, second, nor third fingers could be moved laterally in abduction or adduction, nor could the little finger be adducted towards the ring finger, nor could the thumb be adducted towards the *index*, though abduction of the little finger could be performed normally.

It will be remembered that the deep palmar branch of the ulnar nerve supplies the adductor pollicis, the inner head of the flexor brevis pollicis, all the interossei, and the two inner lumbricals. The four dorsal interossei abduct the index and ring fingers away from the middle finger, and move the middle finger laterally, in both directions, while the outer two palmar interossei adduct the first and ring fingers towards the middle finger, and the third palmar *interosseus* adducts the little finger towards *the ring* finger. The deep palmar branch of the ulnar, after supplying the hypothenar muscles, passes deeply to follow the course of the deep palmar arch, crossing the metacarpal bones just below their heads. It is here that prolonged and repeated pressure against the inner side of the palm damages the *deep palmar* ulnar branch, and the recognition of this condition depends on the loss of the lateral movements of the three middle fingers, and of adduction of the *thumb* and *of the little* finger, while abduction of the *little finger remains* normal, and there is no pain or sensory paralysis. *A rare* abnormality in the nerve supply of the two outer *dorsal* interossei is sometimes met with, as I have seen on *three* occasions, when these are supplied by the median nerve, and consequently in such a case these two muscles *would* escape paralysis from pressure on the *deep palmar* ulnar branch.

PYORRHOEA ALVEOLARIS.*

BY

HUMPHREY HUMPHREYS, O.B.E., *M.C.*, M.B., CH.B., M.D.S., L.D.S.,

HONORARY SURGEON, BIRMINGHAM DENTAL HOSPITAL.

THE object of the following remarks is to bring into focus such knowledge as we have on the subject of pyorrhoea, some important additions to which have been made in the last year or two. The inaccurate and vague nature of its title is perhaps justified partly by the lack of certainty that shrouds its pathology, partly by its very general use, and I shall not devote time to a description of its signs and symptoms. I shall deal only with the condition most usually understood by "pyorrhoea alveolaris," the special features of which are its general distribution over the mouth and its extreme chronicity. This limitation will exclude from my purview, on the one hand, localized conditions such as the gingivitis, so often seen round the front teeth in mouth-breathers, and inflammation due to local injury, such as tooth restorations, dentures, and orthodontic treatment; and, on the other hand, the acute general conditions such as may be caused by the chemical poisons mercury, phosphorus, and iodine, and special infections like those that produce ulcerative stomatitis, "trench gums," etc. We are left with a condition which, though the clinical picture varies from case to case, has as its lowest common denominator a progressive loss of the tooth-supporting structures, characterized by the two features already mentioned — general distribution and extreme chronicity.

PATHOLOGY.

Perhaps the most important fact in its pathology—which I think we may now safely regard as established—is a negative one: that is, that no specific organism plays the part of *causa causans*. It is now pretty generally accepted that the organisms present are those non-specific germs normally to be found in the mouth, generally streptococci and staphylococci, sometimes spirochaetes and fusiform bacilli. One qualification should perhaps be added. The formation of calculus is a constant and, as I shall show, a vitally important feature of the disease; and the work of Bulleid,[1] since confirmed by other workers, shows that the *Leptothrix buccalis* plays an essential part in calculus formation, and may thus perhaps in a sense be regarded as a prime cause in the production of pyorrhoea. Our conception of the sequence of the pathological changes involved has been much clarified by the researches carried out in the last few years at the Bland-Sutton Institute of the Middlesex Hospital by Warwick James and Counsell,[2] and by other workers, both in that institute and elsewhere. The most important points now made clear are:

(*a*) That the condition commences on the interdental septa and thence spreads both vertically into the periodontal membrane and laterally on to the labiobuccal and lingual surfaces.

(*b*) That the initial lesion consists in a deep proliferation of the gingival epithelium at the expense both of the gum corium and of the periodontal membrane, and that *pari passu* with this deep proliferation goes a superficial desquamation, resulting after a time in the formation of a "pocket," which thus, throughout the whole course of the disease, continues to be lined with epithelium. (The discovery that normal healthy gum is attached to the enamel[3] has compelled us to abandon the conception of a normal "trough" between the gum and the crown of the tooth.)

(*c*) That calculus or "tartar" is invariably present, though not always in sufficient quantity to be detected macroscopically.

(*d*) That absorption of the alveolar bone and periodontal membrane is secondary to the primary epithelial change.

(*e*) That the discharge of pus from the pockets instead of being, as the name of the disease implies, an essential feature, is to be regarded as a complication which, as we know from clinical experience, does not occur in a large proportion of cases. When it does occur it is due to a secondary infection of the pockets by pyogenic organisms with a positive chemiotaxis. Of course, when the pockets have become large a discharge of some sort can generally be expressed from them, but this is not normally pus, but the so-called materia alba, and consists chiefly of food debris and masses of putrefactive organisms.

CAUSATION.

It is still considered by some that in pyorrhoea we have to deal not with a single disease, but with a group of diseases linked together by the fact that they all attack the same organ. This is suggested partly by the variation in the clinical picture, partly by the difference of the bacterial flora in different cases, and partly by analogy with other groups of imperfectly understood diseases, such as chronic rheumatism and rheumatoid arthritis. But just as physicians now appear to regard rheumatoid arthritis and chronic rheumatism more and more as due in nearly all cases to infection from some focus in the body, so I think we are now justified in believing pyorrhoea to be a single disease, and it is certainly a great aid to treatment if we can take up this positive standpoint. The differences we observe in the clinical picture must, then, be regarded as due to a difference in the reaction of the patient rather than to a difference in the cause. As in all other diseases, causes divide themselves into a predisposing group and an exciting group. Most of the hoary controversies between the advocates of a general or systemic and those of a local origin of pyorrhoea have had their root in the failure to appreciate that both a predisposing or general and an exciting or local cause must always be present in every case.

Predisposing Causes.

The first of these is the essentially transient and temporary nature of the teeth and their supporting structures, a physiological fact due to the evolutionary history of the mammalia. The reptiles from which they sprang are polyphyodont—that is, they have a succession of teeth limited in numbers only by the life of the individual; each set after a short period of use is cast off and replaced by another. In that class of reptiles (the Theriodontia) from which it is believed that mammals were evolved we see that the life of each set of teeth became more and more prolonged, till in some species two sets were sufficient for the normal life of the individual. This arrangement became stereotyped in mammals, and all the sets of teeth after the second were suppressed. But throughout the mammalia, if an animal lives much beyond its normal allotted span, there is a tendency for its teeth to become lost, till it finally becomes edentulous. The exceptions are teeth of persistent growth, and if they are so arranged that no wear reduces their size these teeth continue to grow larger throughout life—for example, the tusks of elephants.

The loss of the permanent teeth due to wear and the atrophy of the tooth-supporting structures is, then, a normal feature of old age, and there is no clinical difference between the loss of teeth as a normal senile change and their premature loss from pyorrhoea in middle life. Of the reasons for this prematurity in the victims of pyorrhoea we are still ignorant. They may act either directly on the tooth-supporting structures, predisposing them to atrophy and absorption, or they may act by encouraging the deposit of calculus, the most vital of the exciting causes. They probably signify some biochemical change in lime metabolism, perhaps due to an altered endocrine activity. In this connexion F. W. Broderick[3] and Weston Price[4] have made some interesting suggestions, pointing out that pyorrhoea becomes more common as caries becomes less common—a contrast that applies not only to the age incidence, but to the type of tooth most severely attacked—and that pyorrhoea is a disease of lime excess in the blood, caries one of lime deficiency. But a coherent explanation of these matters has still to be worked out, and for the present we must be content to realize that there is undoubtedly some unknown predisposing cause which helps to determine why amongst individuals in whom the exciting causes are equally operative some are attacked by pyorrhoea and others remain immune.

Exciting Causes.

While the predisposing causes are still obscure and are not as yet susceptible to treatment, the exciting causes are now beginning to be understood, and, what is more

*A post-graduate lecture delivered in Birmingham on November 8th, 1928.

important, are to some extent capable of being controlled. They may be summed up in the single word "stagnation." Consider the pathological picture whose salient features I have described. The disease starts in the interdental spaces, the only position where even assiduous oral hygiene cannot entirely prevent stagnation from occurring. It is characterized by the deposit of calculus from the oral secretions, a deposit that can only occur when those secretions stagnate. It commences by a proliferation of epithelium, a process which all over the body denotes, except in the case of new growths (and often in this case also), a local irritant of some sort. The conclusion which obtrudes itself is that stagnation of the oral secretions in the interdental spaces—assisted, as we now believe, by the activities of the *Leptothrix buccalis*—produces a deposit of calculus; this, in its turn, acts as an irritant to the epithelium covering the interdental septum, causing it to proliferate deeply and desquamate superficially till a pocket is formed. A vicious circle is now established: the presence of the calculus and the existence of the pocket will still further encourage stagnation, not only of the oral secretions, but of fermentable food debris, and leads in turn to the formation of more calculus and deeper pockets, and the existence of a culture medium for bacterial growth. Infection from this, spreading along the blood vessels and lymphatics which pierce the crest of the bony interdental septa, produces absorption of the bone till every detail of the pathological picture is accounted for. If this conception covers the facts we have only to consider the factors which favour oral stagnation.

1. The first and most important of these is modern diet. The teeth and jaws of man were evolved before cooking was invented, and the friction of a natural diet on the gums, with the thorough mastication involved by it, promotes a flow of the oral and salivary secretions sufficient to prevent any of that oral stagnation which is to some extent inevitable with modern food. The point is well illustrated by comparative pathology. Wild animals rarely if ever suffer from pyorrhoea apart from loss of the teeth in extreme old age. Animals, however, in captivity and domestic species are not infrequently attacked by the disease owing to their artificial diet.

2. Irregular arrangement of the teeth and malocclusion, due either to faulty development of the jaws or to premature loss of teeth, will obviously encourage stagnation, and we find, in fact, that pyorrhoea is more common in such mouths, as it also is in mouths where the saliva is unduly viscid.

3. Dental restorations, whether fillings, crowns, bridges, or dentures which from faulty design or imperfect execution tend to trap food and impede a free flow of oral secretions, will obviously provide an exciting cause for pyorrhoea.

TREATMENT.

It is an axiom that all sound treatment of disease should be directed towards its cause, and not to its symptoms. Over the predisposing causes of pyorrhoea we have as yet no control, and if the conception of its exciting causes which I have put before you is well founded it follows that our sole aim in treatment should be the continued prevention of oral stagnation; and in fact the conception of oral stagnation as its cause rests not only on the evidence of pathology, but on the clinical fact that the therapeutic measures directed against it are the only ones that do produce a permanent result. What measures, therefore, are open to us? We cannot expect to see the adoption of a diet so coarse and astringent that it would be sufficient in itself, and the treatment possible divides itself into surgical and medical procedures.

Surgical Treatment.

The paramount surgical treatment is a complete removal of all the calculus, and this scaling, in the great majority of cases, will have to be repeated at regular intervals. It is obvious that, however thoroughly the calculus is removed, the cause that led to its deposit in the first instance will bring about the same condition again; and the medical measures I shall describe, directed to the removal of that cause, are seldom so thoroughly carried out or so perfectly effective that the need for subsequent scalings will not arise. Another surgical measure of great value is the abolition of any pockets that may exist—that is, the removal of the gum to the level of the floor of the pockets, by the knife, the cautery, or by escharotic drugs. The existence of pockets renders the task of preventing stagnation around the teeth, which is the goal of all our treatment, peculiarly difficult, and the clinical results of gum resection are uniformly excellent.

Medical Treatment.

The surgical measures I have mentioned, though they arrest the course of the disease for the time being, cannot be expected to effect a permanent cure. The patient will be no less liable to oral stagnation, a fresh deposit of calculus, and a recrudescence of the disease than he was before, and the surgical measures must be followed up by some daily measure of oral hygiene which will, as far as is humanly possible, prevent a recrudescence of pyorrhoea by preventing oral stagnation. No measure that is not repeated daily can hope to maintain a permanent cure, and it follows that effective medical treatment can only be undertaken by the patient, and will be effective in proportion to the diligence we can persuade him to practise.

There are three methods I have tried in my own practice: (1) daily irrigation of the gums and interdental spaces with a powerful spray from an atomizer; (2) daily cleansing of interdental spaces, and any pockets in the gum that are not resected, with hydrogen peroxide applied through a fine root syringe; and (3) saline massage. The salt promotes a flow of serum into the pockets and interdental spaces by osmosis; the massage first squeezes this out and then causes the pockets to fill up again with serum. Stagnant areas are thus sluiced out by the patient's own serum.

Daily medical treatment by the patient himself somewhat on these lines is, I believe, the only treatment likely to give results that are permanently satisfactory. The other forms of medical treatment are mostly aimed at what we now know to be complications of the disease, such as infection of the pockets with pyogenic organisms, rather than at the primary condition; and conditions such as pus formation usually disappear spontaneously in response to the measures I have mentioned. If they do not, then a course of special treatment may sometimes do good—either the old method of treating the pockets with caustic drugs, or a course of vaccine therapy, or ionic medication, or treatment with high frequency current. Nothing is more easy than to effect a cure of pyorrhoea if by cure is meant an arrest of pus formation. Only too often the so-called cures have meant little more than success in eliminating this particular complication of the disease for the time being.

PYORRHOEA AND SYSTEMIC INFECTION.

The time is not far distant when physicians were addicted to ordering the wholesale extraction of teeth attacked by pyorrhoea, in the interest of the patient's health. To-day the attitude of medical men appears to have changed, and we find their attention directed to teeth with non-vital pulps as the most important dental factor in general disease, together with an implicit reliance on *x* rays as the only reliable method of diagnosis. Except that I believe radiographic evidence, taken alone, to be wholly inadequate and often misleading, I am fully in agreement with this attitude. The cases in my own clinical experience where teeth with pyorrhoea have damaged the general health are an insignificant minority compared with the vastly greater number where such damage has been wrought by non-vital teeth, and I find that physicians with sufficient knowledge of dental pathology clearly to distinguish between the two have the same experience. Weston Price, in the most extensive and important study of the dental factor in systemic disease yet published,[1] goes even further and appears to regard active pyorrhoea as evidence of the establishment of a local quarantine or immunity reaction to the rheumatic group

of diseases. Stanley Colyer has published a book[5] taking the opposite view, and regards the alveolar bone in all cases of pyorrhoea, even where no pus is obvious, as infected. Unfortunately, in the cases he cites as evidence of improvement in health following extraction, he fails to distinguish between non-vital and vital teeth, and this seriously impairs their value. Lazarus-Barlow[6] found that over 80 per cent. of cultures taken from the bone below the floor of a pyorrhoea pocket were sterile.

While it remains true that active pyorrhoea does not adversely affect the general health as much as was formerly believed, and far less frequently than apical infections, it is not to be thought that it is wholly innocuous. Its ill effects are most often seen in diseases of the digestive tract, as its toxic products drain into the mouth rather than into the blood; very few cases have occurred in my clinical practice where diseases of the rheumatic group were produced.

The relatively innocuous nature of pyorrhoea compared with apical infections is usually explained as the difference between an open and a closed infection, the toxic products of pyorrhoea draining freely into the mouth and the bacteria being killed by the gastric juices, while the toxic products of apical infections must of necessity find their way into the system. But there is another and more significant difference between the two conditions. An infection of the gums is freely exposed to all the defensive mechanisms of the body, phagocytes, antibodies, and antitoxins, which in most cases constitute an adequate defence. But an infected pulp chamber constitutes a stronghold for bacterial growth, completely protected from all the natural defence forces of the body, where germs can multiply and discharge their toxins and themselves into the system with impunity.

NOTES ON A PEDIGREE OF AMAUROTIC FAMILY IDIOCY (TAY-SACHS DISEASE).

BY

D. D. STENHOUSE STEWART, M.R.C.S., L.R.C.P., D.O.M.S.,

HONORARY OPHTHALMIC SURGEON, VICTORIA HOSPITAL FOR SICK CHILDREN, HULL.

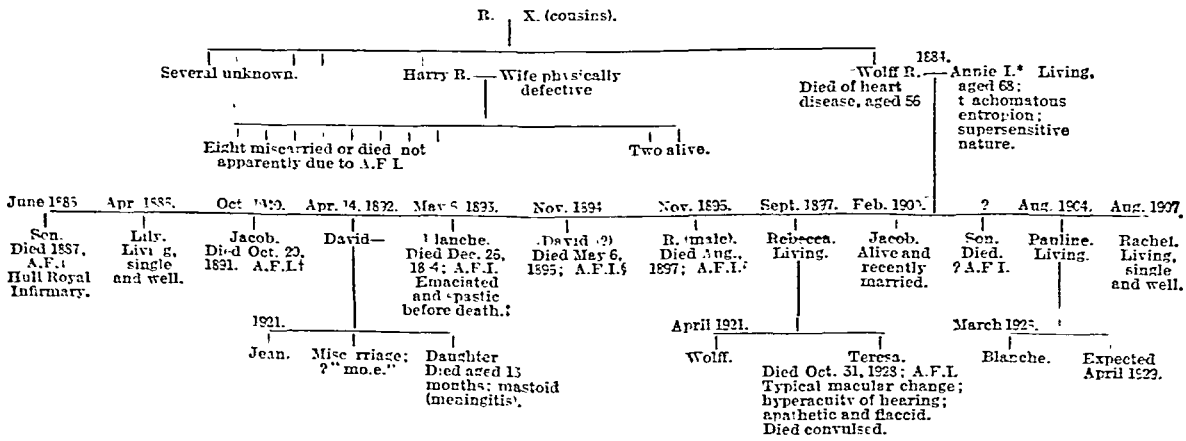
INTEREST in this disease appears to have waned during the past twenty-eight years, and references to the condition are as few during this period as they are plentiful in the twenty years succeeding its first description by Waren Tay in 1881. The condition has apparently been shelved as incurable, largely because it seems to develop prenatally, and it has been impossible previously to forecast that the offspring of any particular Jewess was liable to this affliction.

It has been my good fortune to see at the Hull Victoria Hospital for Sick Children a case of this disease which has proved on investigation to represent the second generation of the classical R—— family. Their vicissitudes were recorded by Mr. Kingdon of Nottingham; of twelve children, six died of this complaint, and in two cases extensive *post-mortem* examinations were performed by Dr. Risien Russell.

Of the remaining six, the eldest daughter is unmarried; the elder son has one living child, one pregnancy terminated apparently in a "mole," and one other child died of meningitis secondary to mastoid trouble. My patient was the second child of the next daughter. I do not intend to report the case fully, as it followed so typically the abler description of its uncles and aunt published by Mr. Kingdon in Volume 80 of the *Transactions of the Medico-Chirurgical Society*. Though flaccid throughout, the patient died convulsed. A boy born to the same mother seven years ago is alive and well.

The next son has married recently, shortly before he knew of the dangerous heredity, and he is disinclined to procreate on this account. The next living member of the family is a woman, who has a healthy daughter aged 2½ years, and is pregnant for the second time, expecting to be delivered in April. The last is a woman of 21, and unmarried.

My object in publishing this pedigree is twofold. First, I consider that the appearance of the disease in the second generation is of general interest, and if it should occur elsewhere in the family it will be important to determine whether or no the succession is solely through the distaff line. Secondly, I desire the consensus of opinion of my colleagues on the manner they think best of meeting the situation. Should Jacob practise rigorous contraception? Should Rachel be advised against matrimony? Will the profession offer any suggestions as to the ante- and post-natal treatment of Pauline's expected child, and any future pregnancies of hers, Rebecca's, or Rachel's if she marries? Kingdon suggested that the dietary of the mother be investigated, and that the babies be weaned from birth, but that was at a time when the disease was regarded as familial rather than hereditary.



* Other members of this family have no abnormal history so far as known.

COMPLETE INVERSION OF THE URINARY BLADDER.

BY

C. BURGOYNE PASLEY, F.R.C.S.I.,

CHIEF SURGEON, FEDERATED MALAY STATES.

COMPLETE inversion of the urinary bladder is a condition of such extreme rarity that the publication of the clinical details in such a case would seem to be warranted.

An undersized, rather poorly nourished Chinese girl, aged 15, with a facies suggestive of hereditary syphilis, and mentally very stupid, was admitted to hospital on August 10th, 1927.

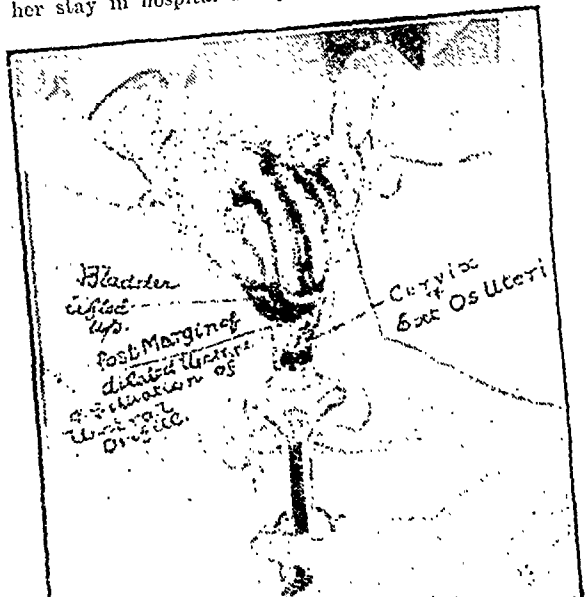
History.—About two months previously the patient had noticed a small and tender swelling between the vulvae; this she had "pushed back." There was apparently a recurrence some five weeks later. About two days before her admission she was carrying two heavy casks of water when she felt something "give." On reaching home she found a large mass between the vulvae. On the following day she remained in bed and attempted to push back the mass, but failed.

On admission to hospital she was seen and examined by the lady medical officer, Dr. Hewitson, who concluded that the protruding mass was possibly the urinary bladder. Shortly afterwards I saw her, and, under chloroform anaesthesia, made a thorough examination.

Condition on Admission.—I found that the protruding mass was without doubt the entire urinary bladder inverted. The mucous membrane was intensely red and inflamed, bleeding on palpation. On gently raising the mass urine could be seen flowing from the ureteral orifices, which were visible just inside the posterior margin of the enormously dilated urethra. Vaginal examination showed that the hymen was absent, the cervix normal, and the uterus small and normally placed. The anterior fornix was obliterated.

Having thoroughly cleansed the parts with warm sterile saline, I returned the protruding mass by steady and gentle pressure. Digital examination proved that no growth of any sort was present. The urethra easily admitted my thumb. The patient was put to bed with buttocks raised, and for a few days the bladder was washed out with 1 in 2,000 acriflavine. She was kept in the recumbent position for three weeks, by the end of which time she seemed able to retain her urine.

At her own request she was permitted to leave hospital, and was instructed to return at once should inversion recur. During her stay in hospital her pulse and temperature remained



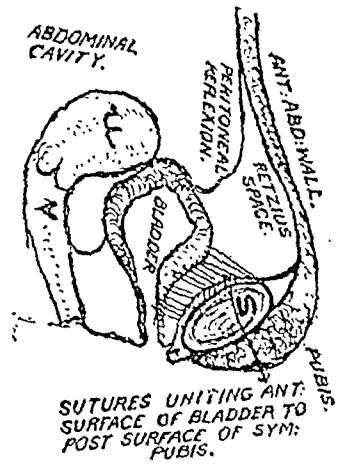
normal; the urine also was normal. I was most disappointed not to have been able at this time to obtain photographs of the condition.

The patient was readmitted to hospital on September 23rd suffering from bronchitis and subtertian malaria. The next day I was sent for, as, following a severe fit of coughing, the bladder had again inverted. She was anaesthetized and photographs were obtained which clearly showed the conditions present.

The bladder was again replaced and the patient was returned to bed, quinine in 10-grain doses being ordered.

It seemed evident that some form of operation was required to prevent further recurrence. A search through all available literature failed to give any information, save an article entitled "Prolapse of urethra in female children," by Thomas N. Hepburn, F.A.C.S., published in the *American Journal of Surgery* for March, 1927 (p. 400), wherein the writer very clearly describes an operation. I determined to try a similar technique.

On October 10th, under general anaesthesia, the space of Retzius was freely opened up. The peritoneal reflection from the anterior surface of the bladder was defined and drawn upwards. The bladder was gently grasped with rubber-protected forceps and drawn upwards. The posterior aspect of the symphysis pubis was lightly scarified. The anterior surface of the neck of the bladder was rubbed with gauze and then firmly sutured to the pubis. The wound was closed without drainage, and dry dressings were applied. It was noticed that this procedure had the effect of drawing up the urethra, which before operation was pouching.



The patient suffered from considerable post-operative vomiting, but no sign of prolapse of the urethra or bladder occurred.

It will be interesting to see if this operation cures the condition. I should be thankful for any information bearing on the case, both as regards incidence, causes, and treatment.

A CHYLOUS MESENTERIC CYST.

BY

GILBERT I. WILSON, B.M., B.CH.OXON., F.R.C.S.ED.,

LATE SENIOR HOUSE-SURGEON, MANSFIELD AND DISTRICT HOSPITAL, NOTTS.

THE following case is noteworthy on account of its rarity, and of the satisfactory immediate result of conservative operative treatment.

A boy, aged 8, was admitted to Mansfield Hospital on April 3rd, 1928, from a neighbouring sanatorium "for relief by laparotomy of ascites due to tuberculous peritonitis."

The first symptoms had been noticed two years previously. The boy was developing a ravenous appetite, especially marked in the early part of the day, and was unusually sleepy in the evening. He would "eat all day"—a mixed diet with an excess of bread, butter, and potatoes—and then sleep ten or eleven hours each night. Shortly after this the abdomen was observed to be rather large, but the increase had been much more marked during the last six months, and it was not until this period that the boy became thin. The bowels were opened each morning urgently following a slight griping sensation; nothing abnormal was noted in the stools. The boy played games, and his general health remained fairly good.

Previous to these symptoms he had been an exceptionally healthy child, being 11 lb. at birth, and but slightly troubled by measles and chicken-pox. When 6 years old (six months before anything of the present trouble was noticed) he broke his leg, but no concomitant injury to the abdomen or back was noted or remembered.

Condition on Admission.—The patient was very thin. No irregularities were palpated in the very large abdomen, but percussion revealed that the umbilical region was as dull as the flanks, the only resonant area being in the epigastrium. There was no thought, however, of questioning the diagnosis.

Operation.—The abdomen was opened through a subumbilical incision, but no fluid was found. Across a soft, white, cystic swelling was stretched a band of small gut, rather bluish in colour. By palpation the swelling was found to extend upwards, pushing the transverse colon, great omentum, and stomach well up under the diaphragm. Laterally the cyst extended behind both ascending and descending portions of the colon; it was pouched in the flanks, thereby becoming trilocular, but all parts communicated freely. In the pelvis were coils of gut. The cyst wall was uniform, and by pinching it was found to be extraordinarily thin. The contents appeared to be opalescent in thin layers, white in thicker, and a diagnosis of chylous mesenteric cyst was arrived at. A small opening was made, and four and a half pints of fluid, exactly resembling milk, was drained off. The opening was closed by ligature, the cyst wall being so thin that the finer stitch holes caused leaks. A certain quantity of fluid was left behind, probably less than a pint. The abdomen was closed. Convalescence was uneventful.

Analysis of the fluid gave the following main facts: specific gravity 1,013; faintly alkaline; total solids 9.58 per cent.—ash 0.9 per cent. (sodium chloride, trace of potash and phosphates), fat 4.05 per cent., protein 3.50 per cent. (almost wholly serum globulin and albumin); there were traces of blood cells, with an excess of *mononuclear types*; *no organisms* were found. This is within the limits of composition of pure chyle. The fat was in a very finely divided state, a many times finer emulsion than cow's milk.

Subsequent Progress.—The boy left for home on the sixteenth day, a detailed diet having been prescribed, largely, but not wholly, fat-free. He was a most depressing sight—pinched face, splayed-out ribs over a flaccid, rather scaphoid, abdomen, and match-like legs. Five weeks later (May 22nd, 1928) the change in the child surprised me, and I regretted not having taken the weight (now 4 st. 3½ lb.) and the waist measurement (now 26 in.) previously. The thorax and abdomen were within normal limits of shape, a moderate layer of subcutaneous fat had appeared, and the boy was now of lively disposition. The clinical signs of cyst or fluid were doubtfully obtainable.

Nine weeks later (July 28th, 1928) the weight was 4 st. 5½ lb. and the waist 26½ in. There seemed now to be definite evidence of a flaccid cyst in the abdomen, and I should think that the fluid is collecting again very slowly.

In discussing the probable origin of the cyst I must express my great indebtedness to Dr. G. Payling Wright of University College Hospital for references to the literature and many suggestions of practical value.

The cyst may be classed broadly as mesenteric, and may, therefore, be primarily chylous, or due to an effusion of chyle into a preformed cyst. C. N. Dowd[1] reviews the subject, and is of opinion that the latter view is correct. If this is so, "false" cysts—inflammatory, parasitic, neoplastic, and dermoid—can hardly be applicable to this case, leaving traumatic and "true" mesenteric cysts only to be discussed.

Of the "true" cysts those suspected to be of urogenital (Wolffian) or enteric origin are lined with epithelium (sometimes very flattened), and although this has been described, the present cyst was so thin-walled, and under such low tension, that there can be little doubt that the wall consisted solely of endothelium and the barest supporting framework of areolar and fibrous tissue. Therefore, it would approach the lymphatic cyst (comparable to a cystic hygroma, which it did not in the least resemble), or a mesocolic cyst (formed of layers of mesentery which failed to fuse after the rotation of the gut in the embryo). Theoretically the superficial position of the cyst, lying against the small gut anterior to the mesenteric vessels, fits in with the mesocolic theory, but I have found no definite evidence that such cysts ever occur.

A traumatic cyst should be associated with adhesions, which were not found. Such cysts are said to occur after a blow on the spine, causing rupture of the receptaculum chyli or thoracic duct. A novel suggestion may be of interest in this connexion—namely, that the condition was one of retroperitoneal effusion of chyle held up by the more firm attachments of the peritoneum to the diaphragmatic, pelvic, and transversalis fascias than to the lumbar and perinephric fascias. However, I have not been able to confirm that these attachments are more firm.

There remains the view that the condition might be primarily chylous—that is, a cystic dilatation of a chylous lymphatic duct, due to obstruction possibly from traumatic or tuberculous fibrosis. This, a simple view at first sight, presents the difficulty that there is such a free anastomosis between ducts; even the entrance to the receptaculum chyli is usually by two or three channels. Had a cure been obtained, the only reasonable explanation would have been that a partial valvular obstruction in a duct had been overcome by complete relief of tension, but a cure now seems a doubtful possibility.

One can therefore only consider three likely explanations: (1) effusion into a preformed mesocolic cyst; (2) a true obstructive cystic dilatation; (3) a retroperitoneal effusion. In view of the very extensive nature of the cyst the last view cannot be put aside lightly. Finally, as the condition may require further surgical intervention, suggestions as to procedure and investigation at the time would be of considerable value.

I am indebted to the kindness of Dr. Arthur Hunnard for permission to publish this case.

ELECTROTHERAPY IN NON-GONOCOCCAL CERVICITIS.

BY

C. F. ORR WHITE, M.R.C.S., L.R.C.P., D.M.R.E.,

MEDICAL OFFICER IN CHARGE OF ELECTRO-THERAPEUTIC DEPARTMENT, ROYAL NORTHERN HOSPITAL.

BY means of the electrical treatment detailed below it is usually possible to clear up cases of discharge from the cervix and urethra where douches and other means have failed.

In hospital practice diathermy is applied to the cervix and urethra as a routine for the first four sessions, Dr. Cumberbatch's special technique being employed. This kills any gonococci which may remain and stimulates internal secretions to combat toxins, but is not essential in non-gonococcal cases. During the next six sessions a well-lubricated zinc or copper electrode an inch and a half long by three-sixteenths of an inch in diameter (at the end of which is placed a circular disc to insulate the parts round the introitus urethrae) is introduced into the urethra; an indifferent pad electrode, eight inches by six, and half an inch thick, soaked in salt solution, being placed over the lower abdomen. The urethral electrode being steadied by a suitable stand the cables are connected to the electrodes and the galvanic current slowly turned on till a strength of 5 to 7 ma. is reached. The positive pole is always connected to the urethral electrode, and after twenty minutes' treatment the galvanic current is slowly turned off. More than 5 ma. should not be used at first as the patient may complain afterwards of pain on micturition.

When treatment of the urethra has been completed a speculum is introduced into the vagina till the cervix is clearly seen, and an electrode of the same shape and material, but a foot in length, is passed down the speculum and introduced gently about three-quarters of an inch into the cervix; if endometritis is present it may pass an inch or more. A piece of rubber tubing is slipped over the electrode as far as the cervix, thus preventing any short-circuiting with the speculum or possible burn of the vagina. The indifferent electrode being in position as before, the negative cable is attached to the electrode passing to the cervix and a current of 15 to 25 ma. passed for twenty minutes. This not only causes copious secretion from the cervical mucous membrane and draining away of pathological products, but has a caustic action as well.

At the last two sessions, by which time the discharge has become less or nearly ceased, the positive cable is applied to the electrode in the cervix, and the current turned on till 40 ma. is slowly reached. This current is passed for twenty minutes and slowly turned off. The result is to dry up the cervical secretion, and at the same time (according to type of electrode used) introduce into the cervix zinc or copper ions, both of which are strongly antiseptic. The average number of treatments necessary is about a dozen, but this will depend on the amount of cervical and urethral inflammation and induration, which within limits vary with the duration of the discharge. This brings out the importance of early treatment, which makes for a good prognosis. In every such case it is essential to treat the urethra.

I will illustrate the results of treatment by giving two typical cases.

CASE I.

A woman, aged 21, complained of discharge and frequency of micturition (the date of onset was not stated). Treatment was begun at the Royal Northern Hospital on September 13th, 1926. On examination the cervix was seen to be congested and indurated, maculae were present on the vulva, and pus exuded from the cervix. A smear showed no gonococci. Only slight improvement followed treatment with silver nitrate douches. She was sent to my department on November 15th, 1926. The urethra was swollen, the cervix red and swollen, and thick pus was obtained from both. Three treatments by diathermy caused the cervix to become less red and swollen. Ionization was performed weekly till December 26th (eight treatments), when no pus was to be seen in either cervix or urethra. The patient reported in a fortnight and again in a month, and at the last examination some chronic thickening of the cervix was found, with rather excessive clear mucous discharge, from which the patient had no discomfort whatever. No pus was found, and cultures from the cervix were negative.

CASE II.

A married woman was treated for cervical discharge six years previous to September, 1926, when she came to the Royal Northern Hospital complaining of burning pain in vulva and vagina; she had noticed no discharge. A smear taken showed no gonococci. After douches had failed to benefit the patient she was sent to my department on November 1st, 1926. I found the cervix red and swollen, with pus round the os and on the vaginal walls. On November 15th a small erosion was seen. Eight treatments by diathermy cleared up the erosion and the pus became less thick, though there was now some to be seen in the urethra. After four treatments by ionization no pus was seen in the urethra and the cervix was much less red and swollen. After eight treatments there was complete cessation of discharge and the cervix appeared normal.

The patient reported a month later that she felt quite well; the cervix and urethra both appeared quite normal; no chronic thickening was seen.

I could only treat these cases once a week, but twice a week would be more efficient and would lessen the number of sessions required. I hope these notes may be of service to those in general practice who use a galvanic apparatus.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PSEUDOCYST OF THE PANCREAS.

PSEUDOCYSTS of the pancreas are undoubtedly rare. The following clinical details of a case therefore seem worthy of record.

A boy, aged 7 years, had the upper part of his abdomen crushed by a cart. He was taken to another hospital, and was detained. The following two days he vomited some bright red blood, but otherwise his condition was normal. X-ray examination of his chest revealed no bony injury, and after being kept under observation for one week he was discharged apparently normal. Ten days later he had an attack of vomiting, and the following day he had pain in the left side of his abdomen. The vomit this time showed no traces of blood. He was brought to this hospital, and on examination the following condition was revealed.

A large swelling was present in the left epigastric region; it was tender on palpation, was rounded off, and extended almost to the umbilicus. The percussion note was dull, and the stomach outline could be made out at its upper border. The tumour therefore occupied the position of the lesser peritoneal sac. The temperature was 100° F., pulse 120. Two days later Mr. Irwin operated. The abdomen was opened by a left rectus incision under local anaesthesia. The transverse colon was greatly distended, and in order to explore the lesser peritoneal cavity ether was resorted to. The mass was found to be an intraperitoneal pseudocyst of the pancreas occupying the lesser sac. It was approached through the gastrocolic omentum. The wall was incised, and the contents of the cavity (blood-stained fluid and a coagulated mucilaginous substance) evacuated. A cavity about the size of a hazel-nut was present in the substance of the pancreas. This cavity was covered by a thin membrane, and had evidently been a haematoma. A drainage tube was left in for two weeks, during which time a clear fluid discharged in decreasing amounts. This fluid on examination contained pancreatic enzymes. The boy made a complete recovery in five weeks.

The origin of the cyst was probably a small haematoma in the substance of the pancreas, caused by injury to the upper abdomen. The haematoma had occupied the cavity in the substance of the pancreas revealed at operation. This would be in agreement with the original article on the subject by Jordan Lloyd in the *British Medical Journal* (1892, ii, p. 1051). He was the first to point out that the majority of such cysts following abdominal injury were not true retention cysts of the pancreas. He reported two cases, both occurring after abdominal injury—one three weeks and the other three months. Both cases had been discharged from hospital, and were readmitted subsequently. He believed both to be associated with injury to the pancreas, probably by pressure against the first lumbar vertebra, but in neither case was the pancreas specially examined for evidence of injury.

Of 117 cases collected from the literature by Körte in 1911 there was a definite history of abdominal injury in 33. Among 41 cases collected by Judd in the records of the Mayo Clinic trauma seemed to be an etiological factor in one case only, the cyst occurring two months after the injury. Lazarus produced a cyst by crushing the pancreas of a dog. A haematoma was first formed, which later became an encapsuled cyst containing 100 c.cm. of fluid.

I am indebted to Mr. Irwin for permission to publish this case.

H. A. WARNOCK, M.B., B.Sc.,
Ulster Hospital for Children and Women, Belfast.

VARIATIONS IN THE BLOOD UREA CONTENT.

THE following case is of interest as showing the remarkable variation possible in the blood urea content within a relatively short space of time.

A woman, aged 55, was admitted to St. Luke's Hospital, Bradford, on July 10th, 1928, with a history of renal colic, haematuria, and the passage of gravel. The pain was referred to the left side, but x-ray examination showed a large number of stones in the right kidney, with the left kidney area quite clear. Next day, at an operation, the right kidney was removed. The kidney was enlarged and its pelvis and calyces were almost solidly filled with calculi of varying size and shape. There was so little kidney substance present that the kidney was to all intents functionally useless. Subsequently the patient had a normal convalescence until August 14th, when she complained of some left-sided abdominal pain; the temperature rose to 102° F., and the passage of urine ceased completely. On August 16th no more urine had been passed, and the blood urea was 48 mg. per 100 c.cm. During the next week not more than 3 ounces of blood-stained urine were passed, and the general condition became steadily worse with progressive headache, drowsiness, and vomiting. There was no improvement in spite of treatment by the usual methods. On August 21st the blood urea was 330 mg. per 100 c.cm. During the next week no more urine was passed, and catheterization showed that no urine was present in the bladder. The symptoms became more distressing, but there were no signs of twitchings or commencing uraemic convulsions. On August 28th the blood urea had risen to 500 mg. per 100 c.cm. Then there came a dramatic change in the condition. That day a little blood-stained urine and some stones were passed per urethram, and this was followed by intense diuresis—over 15½ pints of urine being passed in the next sixteen hours. Subsequently there was a steady improvement in the general condition, and urine was passed normally. On September 4th the blood urea was 25 mg. per 100 c.cm.; on September 12th it was 30 mg. per 100 c.cm., and the patient was discharged in a satisfactory condition.

The chief features about this case are the steady rise in the blood urea associated with the progressive development of uraemic symptoms and the remarkable fall in the space of one week from 500 to 25 mg. per 100 c.cm. associated with the diuresis. It is to be noted that this fall was accomplished with one kidney, a tribute to its functional capacity.

I am indebted to Mr. Hughes for permission to publish this case, and to Dr. Ritchie for the blood urea estimations.

Bradford. GEORGE BROWN, M.B., Ch.B.Ed.

IDIOSYNCRASY TO QUININE INJECTIONS.

THE following case of quinine idiosyncrasy in which rather alarming symptoms occurred after intravenous injection for varicose veins, seems worthy of note.

A married woman, aged 65, presented herself as an out-patient at the Skin Department of the Edinburgh Royal Infirmary suffering from varicose dermatitis, and it was decided to treat the causal condition—namely, the varicose veins. Accordingly 1 c.cm. of quinine and urethane solution, containing 0.13 gram quinine hydrochloride and 0.065 gram urethane, was injected into a varix in the lower third of the right leg above the area of dermatitis. Almost immediately after the injection the patient began to cough, and five minutes later she collapsed, falling from a chair to the floor. She was extremely cyanosed, and complained of inability to breathe and a sense of constriction of the chest. The pulse could hardly be felt, and was irregular in time and force. A subcutaneous injection was given of strychnine 1/40 grain and digitalin 1/100 grain. She gradually improved, and her first question was whether quinine had been given. She stated that twenty-four years previously she had taken quinine by the mouth and had suffered from breathlessness; she had been advised never to take quinine again. She was kept under observation in one of the medical wards and was able to return home next morning.

Ten days later she returned and declared she felt none the worse. A firm thrombus was present at the site of injection. The opportunity was taken to perform a cutaneous test with a 1 per cent. solution of quinine hydrochloride. One drop of the solution was placed on the forearm and the skin scarified under it. Sterile water was used as a control. Ten minutes later a definite wheal, surrounded by an area of erythema, was seen. The control showed only very slight redness due to the scarification. A similar test was performed on my own arm and no reaction occurred.

When there is any reason to suspect idiosyncrasy to quinine the simple test described should be employed. I have treated over thirty cases of varicose veins with quinine and urethane solution intravenously, and, apart from the case described, with no untoward result.

Dr. Cranston Low, physician, Skin Department, Edinburgh Royal Infirmary, has kindly granted me permission to publish this case.

A. G. CRUIKSHANK, L.R.C.P. and S.Ed.,
Clinical Tutor, Skin Department, Edinburgh Royal Infirmary.

PARESIS OF THE MOTOR OCULI NERVE.

IN the latter part of their course the third, fourth, fifth, and sixth cerebral nerves are all intimately connected as they traverse the sphenoidal fissure and the cavernous sinus. At their deep cerebral origin they are also closely related, more especially the nuclei of origin of the third and fourth nerves. The former lies close above the latter in the floor of the aqueduct of Sylvius connecting the third and fourth ventricles of the brain. It is reasonable, therefore, to expect that any peripheral or central lesion of the third nerve will also be accompanied by symptoms arising from complication of any or all of the fourth, fifth, and sixth cerebral nerves. In practice this is the usual experience.

The following case in which symptoms of paresis of the motor oculi nerve alone, unaccompanied by symptoms of other nerve complication, is perhaps deserving of record owing to its comparative rarity.

Eighteen months ago I was consulted by a man, aged 42, who complained of diplopia, the onset of which first became apparent about six weeks previous to his seeking advice. There was a history of syphilis contracted about six years before this date. The knee-jerks were absent.

On examination of the left eye it was apparent that there was slight but definite ptosis of the upper eyelid, together with slight external strabismus. Upward movement of the eyeball was defective, as also was inward movement of the organ. Movement of the eyeball downwards and outwards was unimpaired. On comparing the pupils of both eyes there was obvious mydriasis on the left side. The conjunctiva was perfectly clear, with no sign of venous congestion. Ophthalmoscopy revealed no optic neuritis, retinal changes, or hyperaemia. The right eye was normal. The Wassermann reaction was positive. The fourth nerve was obviously unaffected, since the superior oblique muscle, which causes the eyeball to turn downwards and outwards, appeared to be functioning well. Implication of the fifth nerve was eliminated by the fact that there was no neuralgia either of the supraorbital or any other type. There was no internal strabismus which would be caused by paresis of the sixth nerve affecting the function of the external rectus muscle. The lesion could not have been peripheral, not only because the third nerve alone was implicated, but because there was no venous congestion of the eye or orbit pointing to pressure on the cavernous sinus.

Here, then, was a condition of central origin, affecting only the motor oculi nerve. In view of his history I thought the condition was most probably due to a gumma, situated close to the nucleus of origin of the third nerve in such a position, and of such a small size as not to encroach upon the closely placed nucleus of origin of the pathetic nerve, and to give rise to no retinal changes indicative of intracranial tension.

I gave him a course of injections of grey oil, at weekly intervals for eight weeks, and increasing doses of potassium iodide, orally, three times a day after meals for four months. At the end of that period the troublesome diplopia had completely disappeared, together with the ptosis, and the external strabismus was hardly noticeable with the eye at rest. The pupil reacted quite briskly, and had become the same size as its fellow. The Wassermann reaction, however, still remained positive.

Unfortunately, the later history of the case could not be followed as the patient left the district, and has failed to communicate with me regarding his condition.

D. GORDON ROBINSON, L.M.S.S.A.,
Late Honorary Surgeon, Hull and East Riding Institute for the Blind.

Reports of Societies.

ENDOCRINE TUMOURS.

AT the Section of Medicine (Royal Society of Medicine) on January 15th, with Dr. ARTHUR F. HURST presiding, a paper on the subject of endocrine tumours was presented by Dr. F. PARKES WEBER. A second paper, by Dr. O. Leyton, which had been announced, was not taken, owing to the illness of the author.

Dr. Parkes Weber, who only made certain comments on his lengthy and comprehensive paper, began by remarking that he had taken a great deal of interest in the subject of endocrine tumours since, in the early years of the present century, he had participated in a discussion on a case of suprarenal cortical tumour brought forward by Bulloch and Sequeira. He recalled also bringing before the old Pathological Society a case of primary carcinoma of the liver in which, apparently, bile was secreted by the cancer cells. He found, however, that that case was by no means the first of its nature to be published, and, indeed, it was cases of this kind which first afforded evidence that tumour cells continued to function more or less like the cells from which they originated—that is to say, endocrine functions belonging to the cells from which the tumour originated were continued by the endocrine tumour.

Endocrine tumours must, of course, be exceptionally rare. To get a "full-blown" endocrine tumour it was necessary that the patient be of the right age; if the subject was too old there was no capacity left, and the manifestation of the tumour was blurred. The tumour cells, while probably not equal in physiological power to the normal cells from which they were derived, were in enormous numbers—say one hundred tumour cells to one original cell—and by that very fact were enabled to multiply the physiological action. The same symptoms need not always be evidenced as a result of the same kind of tumour. A person with acromegaly, for example, might react differently, according to age and sex and the different constitution of the parts involved. One of the effects of acromegaly was an extreme thickening of the scalp. The scalp got so big and thick that in order to fit the skull it had to be corrugated. Recently he had had occasion to refer to a case in which this occurred only on one side of the body. His explanation was that in some cases only one side of the body was so constituted that it reacted readily to an endocrine stimulus.

Pineal tumours, Dr. Parkes Weber went on, presented some difficulty. From the pineal tumour there could be no doubt that we got what he called "macrogenitosomia"; the usual term was "macrosomia," but he preferred to reserve this for excessive bodily growth, and to use the other term to express excessive sexual development. Some people thought this to be due to destruction of the normal function of the pineal body, but the fact remained that tumours of the pineal body did certainly produce macrogenitosomia in some cases. Turning to the testes, the speaker said that in modern textbooks it would be found that pathologists stated that certain tumours of the testes looked as if they were derived from the interstitial cells. Unfortunately, all these cases occurred in adults, after general growth had ceased, and therefore one could not expect to get macrogenitosomia; but Mr. Rowlands had lately had a remarkable case of macrogenitosomia in a boy of 9, photographs of which he permitted to be shown. A tumour was removed from this boy, which was pronounced to be a tumour of the interstitial cells of the testes. The boy, previous to removal of the tumour, had adult sexual characters, and returned to childhood afterwards. A point to be noted was that in a number of conditions in men, an upset of the endocrine balance was associated with unilateral or bilateral enlargement of the breast, and in some cases with a certain secretion of milk. This was known to follow pineal tumour, it was known in acromegaly, in traumatisms of the testes, and in some other conditions. One must not argue that because a male developed mammary enlargement therefore he had not got one of these virilism-producing tumours.

Turning to the pancreas, he said that no tumour which produced endocrine symptoms was known in the pancreas until quite recently, although it was known that in some cases of primary cancer of the pancreas the tumour cells resembled those of the islands of Langerhans. Tumours of the thyroid gland scarcely needed to be mentioned; one of the most famous cases in this connexion was published as far back as 1894. There was more difficulty with regard to the parathyroid; some of the tumours might have represented an adenomatous form or an attempt at compensatory hyperplasia. Was there any function of the spleen or parts of the spleen? There was evidence of symptoms produced by the action of the spleen which might be called "hypersplenism" by analogy with hyperthyroidism. The symptoms included haemorrhage and anaemia, but if one wanted to find out exactly what they were one must look to the diseases in which removal of the spleen produced an apparent cure. One rare disease manifested nodules

originating in the Malpighian corpuscles of the spleen; this was accompanied by anaemia, thrombocytopenia, and tendency to haemorrhage, and might prove to be one form of tumour issuing from the endocrine organ, but the subject was too speculative to dwell upon.

When it was borne in mind that an affection of one endocrine gland must almost necessarily cause reaction in others, it was not surprising that the clinical picture might sometimes be obscured by pluriglandular symptoms. Moreover, precocious growth, combined in most cases with precocious sexual development, might be caused by endocrine tumours of the suprarenal cortex, of the anterior lobe of the pituitary gland, possibly of the pineal gland, of the interstitial cells of the testes, and likewise of the ovary. Functionally active primary tumours and tumour-like hyperplasia of the various endocrine glands might be subdivided into those which arose as a pathological manifestation of a compensatory reaction on the part of the body, counteracting a specific hormonic deficiency, and those—specially considered in this communication—which arose independently of any obvious need or stimulation, and were rather the cause of hormonic over-activity, which in some cases might be injurious rather than beneficial to the rest of the body. In both these classes secondary symptoms, including further endocrine symptoms, might be produced by the local pressure and irritation, and, moreover, malignancy might supervene. Non-endocrine tumours might also by local irritation, pressure, or destruction give rise to endocrine symptoms.

Dr. A. F. HURST mentioned the case of a man who, as a result of parathyroid tumour which was operated upon, developed, among other symptoms, the exact opposite of macrogenitosomia. His hair ceased to grow, and he lost all sexual sensation and power. He was given parathyroid gland and recovered completely, beginning again to shave every day, though previously it had been sufficient for him to shave once a month. He had to take full doses of parathyroid over two or three years, and lessened doses over an extended time. Sexual vigour completely returned.

Dr. W. LANGDON-BROWN spoke of some cases of virilism which had come within his experience, and commented on the remarkable fact that these disturbances might be produced by a lesion in the cortex of the suprarenal gland or in the anterior lobe of the pituitary, or both. With regard to the pineal gland, he thought the undoubted effects were rather through the vegetative nervous system than by any endocrine action.

Dr. ARTHUR ELLIS spoke of another case bearing on Dr. Parkes Weber's reference to tumour cells in primary cancer of the pancreas resembling those of the islands of Langerhans. He also asked about the clinical syndrome associated with tumours of the anterior lobe of the pituitary.

LIGHT THERAPY IN MENTAL HOSPITALS.

AT a meeting of the Section of Psychiatry of the Royal Society of Medicine on January 8th, with Sir MAURICE CRAIG in the chair, a discussion took place on light therapy in mental hospitals.

Dr. H. DOVE CORMAC (Macclesfield), in opening, said that only sixteen mental hospitals had apparatus for administering artificial sunlight; eight others hoped soon to have an installation, though it was now five years since actinotherapy was first used at Horton Mental Hospital, under the direction of Colonel Lord. During 1925 an investigation was undertaken at his (the speaker's) hospital as to the results of irradiation of about 50 cases, the patients having been treated for periods of from two weeks to two months. An 80-ampere carbon arc was used, the electrodes being high-intensity carbons. Six to eight patients were treated at a time, the whole body being irradiated. All suitable admissions during the year were so exposed. These did not include any cases of epilepsy, mania, or general paralysis of the insane. Five minutes' exposure to the front of the body and the same to the back was given at the commencement, until a maximum of thirty minutes was reached, the arc being 3 ft. from the patient. The metabolic rate and the pressure and differential count of the blood were recorded before, during, and after treatment, and a weekly note was made of body weight and of mental variations, appetite, sleep, and skin condition. There was a marked and general increase of body weight after the treatment, to an average of 3½ lb. per patient. Generally also the appetite improved, and in most of the patients there was more muscular activity, with an accession of cheerfulness after the treatment. The metabolic rates and the blood counts showed no constant variation. On the average there was a slight decrease of the systolic pressure. It was soon recognized that such conditions as melancholia with agitation and hyperthyroidism were aggravated by the irradiation. Cases of manic-depressive insanity responded most readily, for the rays led to a material curtailment of the period of depression. Mild cases of melancholia were benefited by the treatment. Delusional cases, with much mental irritability due to the delusions, became more amiable under the rays. In dementia praecox the treatment produced no amelioration of the mental condition, but some of these cases showed greater motor activity and talkativeness. Some declared that the irradiation augmented the bactericidal power of the blood and improved the body immunity. Murray Levick had declared that the neurasthenic symptoms accompanying rickets had been made to disappear under ultra-violet ray treatment. Dr. Cormac reminded the meeting that many so-called neurasthenics were really cases of melancholia with hypochondriacal tendencies. It was now generally held that the ultra-violet rays affected not only the vasomotor system, but also other parts of the vegetative nervous system, such as those controlling the pigmentation of the skin, the fibres supplying the hair follicles, and those affecting the muscle tone. It was justifiable to infer that the whole of the sensory division of the nervous system was influenced by general irradiation. Ultra-violet rays could be said to paralyse certain inhibitions and to produce a general sense of well-being. In some people hypersensitivity to light rays might be an idiosyncrasy, and this possibility should always be borne in mind in deciding individual dosages.

Sir HENRY GAUVAIN explained that his work did not consist in treating mental cases, but perhaps his contribution might have some bearing on that special aspect. Irradiation with ultra-violet rays had a tonic and stimulating action, but its prolonged employment caused progressive loss of response, while excessive exposure to the rays produced depression, listlessness, and exhaustion. Interrupted and periodical exposure to the rays seemed preferable to long courses. In the study of the chemical changes in the blood following exposure to ultra-violet light it had been demonstrated that such exposure was followed by an increase in the inorganic blood phosphate. It had been suggested that the rays might be an important factor in effecting tissue change, and so might improve the nutrition of the grey matter of the brain, thus increasing the mental activity. These facts seemed to have an important bearing on the education of the normal as well as of the subnormal child or ailing child. When planning treatment it should be borne in mind that there were seasonal and diurnal variations in response to the rays. General light baths should only be regarded as auxiliary means of treatment, and should not be held to supplant other methods of proved utility.

Dr. A. C. HANCOCK spoke of his experience of the rays at Horton Mental Hospital in earlier days. He said the carbon arc lamp was cheap to install, and many cases could be treated by it at the same time. In many hospital patients no definite focus of infection could be found, but their general appearance was unsatisfactory. In all with a definite septic focus the results of the ultra-violet treatment were very satisfactory and lasting. A good deal of notice should be taken of what the patient himself said about the treatment; in many cases the remark was volunteered that they felt much better in every way; spontaneous expressions of gratitude were forthcoming from 70 per cent. of the patients. Cases of dementia praecox did not usually benefit by the treatment, but most cases of the simple type were improved. He had come across cases of definite malaise among nurses and patients in association with the administrations; there was a

complaint of giddiness, sweating, etc. Generally speaking, the installation and use of this treatment had been fully justified in mental hospitals.

Dr. G. DE M. RUDOLF (Claybury Mental Hospital) objected to the use of the term "light rays" for the ultra-violet rays. It led to confusion with the light and red ray treatment of Dr. Murray Levick. Ultra-violet radiations having been proved to be of value for certain conditions in general hospitals, they were clearly also of value in mental hospitals for the same conditions. For that reason alone he thought that every mental hospital should be equipped with such installations; 185 patients in Claybury Mental Hospital had had this treatment in the last three years. It had been shown that ultra-violet rays did not of themselves change the metabolism of the body. Experience at Claybury had taught caution in forming a judgement as to the effect of ultra-violet rays on mental and physical disorders. Two types of cases were particularly difficult to judge. The first was that of general paralytics who had previously been treated with malaria and were then subjected to these rays to tone up the body after the course of quinine. It was almost impossible to get adequate control cases. His own impression was that the patients who were given ultra-violet rays improved more rapidly than those who did not have this treatment. The other type of case he referred to was the poorly nourished, pale, melancholic, toxic patient. Treated with the rays soon after admission, it was impossible to know whether their improvement was due to the rest, food and regular method of living in the hospital, or to the rays.

Dr. R. BOURDILLON made a plea for the employment of more visible light in treatment and less ultra-violet radiation. At present most irradiation treatment was done with mixed rays. Tungsten arcs and mercury arcs gave only a fractional portion of the benefit which was traceable to direct sunlight. The value of the burning of the skin was difficult to appraise. Less was at present known as to the effects of visible light than as to those of ultra-violet radiation.

Dr. W. A. POTTS (Birmingham) spoke of the importance, when dealing with mental patients, of giving the treatment in batches, otherwise the fear as to what was going to happen was liable to cancel any mental benefit which might otherwise accrue. He had convinced himself of this by comparing cases treated by arc lamps in hospital with those treated singly in private.

Dr. A. EIDINOW pointed out that the mercury vapour lamp emitted very high intensity short waves, and caused a rapid erythema. The purpose of that lamp was to treat acute and subacute conditions. If such cases were treated with light and radiant energy the results would not be good. In mental patients one was treating chronic conditions, therefore longer rays and visible light and heat rays were indicated. Personally he did not see that mental conditions needed the ultra-violet rays.

Sir ROBERT ARMSTRONG-JONES expressed his approval of the attitude of the Ministry of Health in requiring that the ultra-violet and other irradiations should be given only under competent medical supervision. In the improvement brought about by this treatment there were a multiplicity of factors. It seemed to be contraindicated for tuberculosis.

Dr. ELIZABETH C. MUDIE said she had never encountered any cases of malaise in those associated with the treatment, such as nurses. In only one case in her practice was there a setback, and that was one of conjunctivitis due to carelessness in connexion with the goggles.

The PRESIDENT said that what was most needed at the present time was a definite lead as to the kinds of cases which were likely to benefit from exposure to ultra-violet rays.

Dr. CORMAC briefly replied, remarking that he had not encountered any instances of malaise in the treatment, as mentioned by Dr. Hancock. When a patient had abnormally high blood pressure the ray treatment reduced it, but in cases of low blood pressure the exposure to the ultra-violet rays caused no alteration. When a patient was made worse by the treatment he attributed it to the state of the sensory nerves.

TREATMENT OF DIABETIC COMA.

AN informal discussion of the treatment of diabetic coma took place on January 8th, in the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, with Dr. H. H. DALE in the chair.

Professor E. C. DODDS, who opened the discussion from the standpoint of a chemical pathologist, said that at the Middlesex Hospital reliance was wholly placed upon the dosage of insulin and the blood sugar determinations. When a comatose patient was admitted the blood sugar figure was estimated at once, usually before insulin was given. The patient was then given a dose of insulin, usually 100 units. The important point was that the blood sugar was always controlled. It was possible to work for a time entirely on urine sugar estimations, until the patient was losing his air hunger and the sugar in the blood was getting near normal; but risks were taken in working purely on urine. In showing a chart illustrating the progress of some cases, he pointed out that with all the specimens of blood the alkali reserve was also determined. This determination was worth while because it yielded more information than a simple blood sugar test or a simple test for alkaline bodies in the urine. He then spoke of the patients who, treated in this manner in hospital, did not recover, but died. The reasons for death might be classified as follows: (1) diabetes uncontrollable; (2) failure to respond to insulin on account of kidney damage, with retention of urea, producing a symptom-complex very similar to diabetic coma; (3) failure of circulatory system. It was out of the question to present statistics, because no fair comparison could be made between cases brought into hospital at the commencement of coma and cases which had already been in coma for twenty-four or forty-eight hours. The first category of deaths from uncontrollable diabetes occurred in his experience usually in septic conditions, and *ipso facto* were ruled out of the present discussion. As for the second category, the view that people could die of diabetic coma purely through failure of the kidney was put before the Society some time previously by Professor Snapper of Amsterdam (*British Medical Journal*, May 5th, 1928, p. 759), who found that the urea and non-protein nitrogen was always raised in diabetic coma, and particularly in those fatal cases which did not respond to insulin, so that he concluded there was failure of the kidney which was responsible for death. Experience at the Middlesex had not tended to show that this theory was of any practical importance. A high urea and non-protein nitrogen was extremely common in diabetes, particularly in diabetic coma, and simply from the blood analysis and the evidence of nitrogen retention one could not say that the patients died from uraemia. With regard to the third category, that of circulatory failure, he had watched practically all diabetic comas continuously in the Middlesex Hospital, and had always noticed that patients who died had a low blood pressure and appeared to die from circulatory failure. In one case which he described the subcutaneous injection of ephetonin and pituitrin at half-hour intervals had no effect on the low blood pressure, and circulatory failure was the cause of death in this case also.

Dr. GEORGE GRAHAM gave a particularized account of a recent case of a boy, aged 16, who, after doing well on insulin treatment, suddenly developed coma and was admitted to hospital. He showed charts illustrating the administrations of insulin and glucose, with the blood sugar and other determinations, over a period of six critical days, after which the lad recovered. It was clear that this lad went into coma because he was unable to excrete his acetone bodies; what was wrong with the kidneys the speaker could not say. As for treatment, plenty of insulin and plenty of sugar were given. It was quite clear that the blood in this case flowed with difficulty and was sticky. The haemoglobin, which twenty-four hours after he became ill was 110 per cent., went down to 80 per cent. two days later. Fluid was given intravenously. He believed that some of the patients who died had a condition akin to surgical shock. They could not keep the fluid in their blood. Plenty of fluid should be given, by the mouth if

diarrhoea commenced well before the vomiting. One complication of cholera which he had seen described was gangrene of the feet, and on going to the civil hospital one day he was told by the experienced matron that a patient who had died several hours before showed marked gangrene of both feet. He went to the mortuary, and on lifting the shroud was astonished to see that the feet were of exactly the same waxen colour as the rest of the body; apparently the condition which had been taken as gangrene was merely extreme localized cyanosis.

Bacillary dysentery was common in Shanghai, reaching its maximum in September, but there were only 28 cases of dysentery in the force. Diarrhoea was common also, and few Europeans went through the summer without one or more attacks. Pneumonia was responsible for the largest number of deaths from disease—namely, 13 out of a total of 23. As elsewhere in the tropics, pneumonia in Shanghai was mainly a disease of the hot weather. There was always a possibility of infection owing to the overcrowding in the streets and in public vehicles, combined with the constant spitting habits of the Chinese. As a race they eschewed handkerchiefs, and nothing was more distressing than to find oneself in the middle of a crowd of persons noisily ejecting their bronchial and nasal secretions on to the pavement. Among minor affections various forms of tinea were common, as well as prickly heat and inflammation of the external auditory meatus.

Colonel MacArthur, in conclusion, said that what struck him most on arriving at Shanghai was the position held by the medical authorities. It was not a question of visiting an unwilling staff officer to persuade him to do this or that, but it was a question of the staff officer asking the medical authorities if there was anything further that they wished done, and "what the R.A.M.C. said, went." The gratifying absence of epidemic disease, in spite of the dire prophecies of those most familiar with Shanghai, was due to the ceaseless vigilance of the people responsible for the health of the troops, the excellence of the preventive measures instituted, and the thoroughness with which they were carried into effect.

DIAGNOSIS OF CHRONIC APPENDICITIS.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society on January 3rd, with the president, MR. GEOFFREY BATE, in the chair, MR. H. N. FLETCHER read a paper entitled "Chronic appendicitis and other conditions which simulate it."

Mr. Fletcher, in the course of describing the varieties of pathological appendix seen at operation, mentioned a rather uncommon form, usually seen in children, in which there was very marked hypertrophy of the adenoid tissue of the mucosa and large fleshy glands of the ileo-colic mesentery. Colicky pain of short duration, coming on especially after food, was the principal symptom; it appeared to be due to spasm set up by the hypertrophied mucosa, which did not necessarily show any histological evidence of inflammation. The enlarged glands might cause slight tenderness; it seemed probable that their enlargement was due to absorption of toxins from the appendix. There was no apparent enlargement of glands elsewhere, nor of the tonsils. As regards the diagnosis of chronic appendicitis, the speaker approved the emphasis laid by Sherren and others on the importance of a history of a preceding acute attack, starting centrally; any case in which the pain had started in, or had been confined to, the right iliac fossa should be viewed with suspicion. None the less there were exceptions. Mr. Fletcher had operated on not a few patients with acute appendicitis who insisted that the pain had started in the right iliac fossa, and this was especially the case when the appendix lay in an extra- or retro-caecal position. Again, there were cases of undoubted chronic appendicitis where there had been no acute attack; these were notably of the type in which a faecal calculus caused a mild inflammation of the mucosa surrounding it. Cases not conforming to Sherren's rule should be scrutinized with the greatest care, and every other possible cause be considered in turn, with the help, if necessary, of the *x* rays, and always with a routine microscopic examination of the urine. The investigation must include in its survey the urinary, generative, digestive, and biliary systems. The speaker reviewed 100 cases in which he had operated for supposed chronic appendicitis, and in all of which at least one year or more had elapsed before inquiry was made; 68, or just over two-thirds, had been cured of the pain for which they sought relief, and 32 had had a return of pain, or had minor disturbances which precluded them from being regarded as definite cures. Errors of diagnosis, the majority being cases of tuberculous glands, accounted for twelve of these failures. Sixteen patients, in 5 of whom there was undoubtedly appendicitis also, had ptosis of the proximal colon or congenital membrane formation in it; this probably caused their renewed pain. It was significant that of these 16 patients 15 were females, of whom 11 were young adults. Twenty-nine patients with true appendicitis had dyspepsia also; of these, 22 were cured by appendicectomy; 12 had the flatulent and 17 the painful type. Of these last there was in 8 cases a strong mimicry of gastric or duodenal ulcer, in that the pain was of a severe gnawing, cramping, or gripping type, constant in its time incidence after food, the attacks lasting one, two, or more weeks, with periods of complete relief between. Six of these patients were entirely cured by removal of the appendix. The concurrence of attacks of dyspepsia and the lighting up of appendicular symptoms were noted in several cases. Mr. Fletcher discussed the differential diagnosis between chronic appendicitis, and pelvic, urinary, glandular, cholecystitic, and proximal colon diseases, paying special attention to the last, which was the most common source of error in the female sex. He had found skin hyperaesthesia in appendicitis, involving the neighbouring halves of the tenth and eleventh right dorsal segments far more frequently than any other area, and though the caecum might possibly also be represented in those segments, he regarded such hypersensitiveness as a valuable confirmatory sign of appendicitis.

IDIOPATHIC CARDIAC HYPERTROPHY.

AT a meeting of the Liverpool Medical Institution on December 6th, 1928, DR. NORMAN B. CAPON read a paper on hypertrophy of the heart in infancy, with special reference to the interesting type usually named "idiopathic hypertrophy of the heart in young children."

Dr. Capon described an example of this form of hypertrophy occurring in a male twin baby, aged 4 months; the radiographic and microscopical features were illustrated by lantern slides. The necropsy showed that, in addition to very great hypertrophy and dilatation of the left ventricle, there was abnormal origin of both coronary arteries. The left artery took its origin from the left anterior sinus of Valsalva of the pulmonary artery; the right artery arose from the aorta, but its orifice was situated in the right posterior sinus of Valsalva instead of in the anterior sinus. The thymus was of the normal size for the age. The myocardium, especially the left ventricle, showed fragmentation, disappearance of nuclei, and atrophy; there was no evidence of inflammatory or lymphocytic invasion, nor were any of the special cells described by Ceelen and Riesenfeld seen. Dr. Capon then discussed the circulatory changes which probably occurred during life in the myocardium of the left ventricle as a result of the anomalous origin of the left coronary artery. The investigations of Anrep, Cruickshank, King, Wearn and Hilton, and Eicholtz were referred to, and the probable importance of the Thebesian veins was emphasized. Dr. Capon said that although the literature contained several examples similar to that described, in all of which it might be thought that the supply of venous blood to the myocardium of the left ventricle was the cause of its hypertrophy and dilatation, the following facts must be remembered. Howland and others had described cases of idiopathic cardiac hypertrophy in which the coronary arteries arose normally. Gross had referred to five cases of single coronary artery, apparently causing little or no ill effect. The McGill case (described by Abbott) had demonstrated that a woman was able to live to the age of 60 apparently without cardiac symptoms, although her left coronary artery arose from the pulmonary artery. Dr. Capon concluded by referring to the various theories of the causes of idiopathic cardiac hypertrophy.

SURGERY OF THE OESOPHAGUS AND LUNGS.

LECTURE BY PROFESSOR ZAAIJER.

A MEETING of the Hunterian Society was held at the Mansion House, London, on January 14th, under the chairmanship of Dr. A. WESTERMAN, when Professor J. H. ZAAIJER of the University of Leyden delivered the annual Hunterian Lecture, taking for his subject the surgery of the oesophagus and the lungs.

Professor Zaaijer, who spoke in excellent English, after paying a tribute to John Hunter, gave what amounted to a demonstration, with the aid of lantern slides, of the methods pursued since 1909 in his surgical clinic at Leyden. He began by describing a simplified positive pressure apparatus constructed by his assistants for use in intrathoracic surgery. In passing, he pointed out as a curious historical fact that what twenty years ago was thought to be a new invention was described as long ago as 1543 by the famous anatomist Vesalius, in writing of the danger of suffocating an experimental animal through collapse of both lungs: "But to keep the animal alive one must try to open the windpipe and place therein a tube made from a quill pen or a hollow reed; into this the air must be blown so that the lung swells and the animal gets sufficient air. By a slight blowing the lungs swell so much as to fill the thoracic cavity, and the heart regains its force."

In bilateral pneumothorax, said the lecturer, there was no doubt that such an apparatus was necessary for maintaining life, but he thought that Lilienthal was quite right when he said, in his well-known book on thoracic surgery, that it was unwise not to have regard to positive pressure in unilateral pneumothorax also, because one was never sure that this would not cause very severe symptoms, and at least the danger was lessened by using such a means. Professor Zaaijer described cases in which he had operated successfully under pressure, including one patient who had an immense tumour extending from the side of the neck and front of the chest, where the danger of air embolism when cutting the vessels under the tumour was very great. This patient was operated upon under pressure, and, as subsequent photographs showed, made a very good recovery.

The special anaesthesia outfit employed in the surgical clinic at Leyden was also described and illustrated, including a mask so constructed as to allow the head to lie easily in the side position. The lecturer began carrying out operations for carcinoma of the oesophagus in 1912, having convinced himself as a result of animal experiment that there ought to be a possibility of the resection of such malignant growths. His experience had proved to him the technical operability of carcinoma situated low in the oesophagus, though it was true that he had not many such cases to bring forward, and those in which the operation had shown a successful result, so that the patient lived for some while after, had ended fatally from some recurrence or complication or adventitious circumstances. But he still believed that it was worth while trying to cure a patient with carcinoma of the thoracic oesophagus by operation. Diagnostic and operative technique was slowly but certainly improving. The latest improvement was the mobilization of the stomach, introduced by Kirschner, whereby the stomach could be pulled high up into the thoracic cavity. There was also the more extensive use of the transpleural exploration of the oesophagus, as described by Romanis and others. At Leyden, at all events, they had not lost hope or courage, and he was glad to learn that in England there were optimistic surgeons who shared the same conviction. Some of the lecturer's devices for tube-feeding of the patients subjected to these operations, shown on the screen, were ingenious and elaborate. Professor Zaaijer admitted, however, that so long as it was possible to do so little in the way of radical treatment of oesophageal carcinoma, special gratitude was due to men like Mr. Souttar, who had carried to such a high state of development the palliative treatment of this disease. By the use of flexible metal tubes through the previously dilated tumour area, the patient was given the opportunity of swallowing in the normal way right until the end. It was possible that Mr. Souttar had something of the idea of John Hunter, who, in the case of paralysis of the oesophagus, introduced into the stomach the skin of an eel, extended over a stiff sound, then withdrew the sound, and fed the patient through the soft tube.

Professor Zaaijer then went on to discuss cardiospasm, and the causes, not truly spasm, which gave rise to this condition. He had found a number of such cases following a long-standing abdominal ptosis. He explained by diagrams what he judged to be the mechanics of cardiospasm, and said that he had treated eight cases by the method published by Heller in 1913, splitting the circular muscle bundle of the cardia with fair success and no mortality.

Turning, finally, to the surgery of the lungs, the lecturer described the treatment of bronchiectasis as it had been developed in his clinic. Here appropriate operations had been devised at successive stages according to the extent of the disease, so as to lead up to a climax—that is to say, the operation at any stage might cure the patient, but if it failed to do so, at least it lessened the danger to the patient and eased the task of the surgeon in the wider operation which afterwards became necessary. He began with evulsion of the phrenic nerve. French authors, especially Chauffard, were very well satisfied with this procedure, which they regarded as the operation of choice: in England and Germany, however, the results did not seem to have been very good, and for his own part he had seldom seen a good result from this procedure. The second stage was thoracoplasty, but if this was practised it was advisable to remove also the intercostal muscles. Resection of the periosteum and intercostal muscles was not only in itself valuable in directly improving the therapeutic effect of the thoracoplasty, but in his opinion it lessened the shock of the operation should the thoracoplasty prove insufficient, and an intrathoracic operation in the same territory—which thus became a soft tissue operation—be necessary. Another stage was intrapleural plugging of the pleura after loosening the affected lobe as much as possible from its adhesions to the root. This method could give a complete and lasting cure by compression of the diseased lobe, and the cure was attained with the minimum of danger. Any of the different stages of the treatment might be necessary in a given case, and if one treatment proved ineffective the subsequent more radical operation could be undertaken with less risk and more promise. The lecturer showed a number of remarkable photographs illustrating his technique in these operations and the after-result, an extensive scar, but the retention of a high degree of muscular function.

The PRESIDENT, in expressing the thanks of the gathering to Professor Zaaijer, reminded the audience that the last hostile Dutchman to come to England, Admiral Tromp, sailed the Channel with a broom at his masthead, while his adversary Blake put up a whip. Their Dutch colleague on the present occasion had come, in all friendliness, with both a broom and a whip, the former to sweep away some of the difficulties with regard to lung surgery, and the latter to stimulate thought and action among British surgeons.

Mr. J. E. H. ROBERTS remarked that there was something about the northern countries of Europe which induced the surgeons there to tackle the surgery of the oesophagus. Little was heard here, however, about this noteworthy work, largely owing to ignorance of the Dutch and Scandinavian languages and literature, so that it was very useful to have surgeons coming, as Professor Zaaijer had done, to speak of their work at first hand. The lecturer's set of cases of bronchiectasis had interested him very greatly. He agreed as to the value of minor operations in many cases of unilateral basal bronchiectasis, but the trouble was that surgeons usually had to tackle the condition at a more advanced stage, when it was neither unilateral nor basal.

Sir JAMES DUNDAS-GRANT, joining in the compliments to the lecturer, commented on the absence of any mention of radium. It must not be supposed that radium was going to do away with surgery in this territory, but he thought that one could not neglect the possibilities which radium afforded. Combined with surgery of access, he believed that it would lead to much better results in the future in the conditions which had formed the subject of the lecture.

Reviews.

MODERN BIOLOGY.

THERE are many reasons for extending a welcome to a book on *Modern Biology*[1] by Mr. J. T. CUNNINGHAM. He is one of the leading biologists of our time, and has devoted a long career to the single aim of explaining how living things have become so perfectly fitted to their place in Nature. He began his investigations when Weismann was winning adherents to the doctrine that the machinery of adaptation was inherent in the germ plasm, and could not be influenced by anything which lay outside the germ plasm. From his student days onwards Mr. Cunningham has done his own observing and thinking, and soon came to the conclusion that purposive modifications of the animal body could not be explained if with Weismann we regarded the germ plasm as immune from outside influences. His own early studies, particularly those on the structural modifications which fit flatfish to a life on the sea bottom, convinced him that the essentials of Lamarck's doctrine were true, and that somehow the soma could transfer its experiences and acquired modifications to the germ plasm within it. He gave clear expression to this conviction in the introduction to Eimer's *Organic Evolution as the Result of the Inheritance of Acquired Characters*, which he translated in 1890.

In the present work Mr. Cunningham again tests his Lamarckian convictions by passing in critical review all that has fallen in recent years from laboratories where the processes of life are studied by experimental methods. His is not an armchair criticism; Mr. Cunningham is an experimental naturalist, and is therefore well qualified to estimate the value of experimental results obtained by others. He accepts the opinions of those who believe that the functions of living matter are purely physical and chemical in their nature, but refuses to believe that any combination of physics and chemistry can explain the phenomena of adaptation and evolution. The belief held by Professor T. H. Morgan, based chiefly on his well-known studies of the banana fly, that new characters arise suddenly as mutations, is rejected by Mr. Cunningham as totally inadequate to explain recapitulation in the embryo and the purposive modification of structures. All recent attempts made by experimental embryologists, experimental zoologists, and biometricians to penetrate the secrets of evolution are reviewed and their bearing on present problems examined. Mr. Cunningham reserves his most rigorous criticism for the experiments of those who, like himself, believe that characters acquired by the body can be passed on to the germ plasm, and thus become inherited. His close examination of the laborious and prolonged experiments carried out by the late Professor Kammerer is most searching and valuable. Mr. Cunningham admits that the experimental evidence in support of Lamarckism is still unconvincing, but, on the other hand, the circumstantial evidence in its favour seems to him to be overwhelming.

Mr. Cunningham was the first to apply Starling's theory of hormones to explain how characters acquired by the body or brain might, in the course of repeated generations, be transferred to the germ plasm. He illustrates his conception of the manner in which hormones may serve as messengers from the soma to the gametes by many concrete examples, and those in search of a clear statement of his views will find them in this, his latest work. If Mr. Cunningham could bring forward convincing evidence that such a transference is possible, then he would have proved a matter of the greatest importance to humanity; for if the degree and manner in which parents use their brains influence ever so slightly the facility with which their children use theirs, then the accumulated effect would, in the course of time, lead to an enormous change in human mentality. It was supposed that Professor Pavlov had proved the inheritance of conditional reflexes in animals; this claim Mr. Cunningham finds to be now withdrawn. But in some of Professor McDougall's experiments on rats there is evidence that the experience of adults may be transferred to their progeny, but even in this case Mr. Cunningham admits that the evidence may be explained otherwise than by inheritance of experience.

Some of Mr. Cunningham's experiments, carried out on soles thirty-five years ago, seem to have an important bearing on the interpretation of Professor McDougall's results. Mr. Cunningham observed that when the non-pigmented undersurface of soles was exposed constantly to light the degree of darkening which resulted varied greatly, some fish pigmenting readily, others remaining unchanged. If the tendency to the deposition of pigment was not inherent in the animal no amount of stimulation could produce pigmentation. The power to deposit pigment must first be present; light by itself cannot produce that power. This is in keeping with what is known of the human body; the power of muscle and bone to react to exercise varies enormously from individual to individual; unless that power is present in the individual's body Lamarckism can do nothing; if the power is already inherent in the body Lamarckism can elicit it, and that power, being already an intrinsic possession of the body, is passed on by heredity. The rats which solved Professor McDougall's tests were, we may well suppose, animals which already possessed a superior cerebral equipment for dealing with the experimental situations presented to them, and we may therefore suppose that it was not their experience they handed on to their progeny, but their inherited cerebral outfit. Mr. Cunningham, of course, is fully alive to such a contingency, but perhaps does not emphasize the alternative explanation sufficiently.

Although there are both minor and major matters in which biologists will disagree with views and statements made by Mr. Cunningham, all will admit he has written a book which deserves to be read and studied by medical men as well as professional biologists.

[1] *Modern Biology.* A Review of the Principal Phenomena of Animal Life in Relation to Modern Concepts and Theories. By J. T. Cunningham, M.A. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1928 (Demy 8vo, pp. xii + 244. 10s. 6d. net.)

REQUISITES AND METHODS IN SURGERY.

SENIOR students [illegible] are fortunate in having a few very good [illegible] guidance, and one of these is *Requisites and Methods in Surgery*,[2] by Mr. CHARLES CATHCART of Edinburgh and Mr. JACKSON HARTLEY of Carlisle. It is published by an Edinburgh firm, and may be looked upon as the Scottish counterpart of Russell Howard's *The House Surgeon's Vade-mecum*.

This book by Cathcart and Hartley has a simple, direct, and effective atmosphere of its own. It is written in the careful and lucid style of the generation which was brought up to observe and study clinical facts for itself, and it is not surprising, therefore, that as a guide to general surgical principles, and their application to the details of practical treatment, this account of requisites and methods would be difficult to surpass. In addition, there are to be found references to all the modern methods of investigation on matters within its scope. The context is freely illustrated by means of refreshing pen-and-ink sketches. These have been skilfully executed and impart a homely touch of "local colour": the nurse holding an unruly child, and the occupant of Gatch's bed-rest indicating the Fowler position and others, could be found nowhere but north of the Tweed. The book deals in the main with minor surgery, wounds, haemorrhage, shock, fractures, dislocations, tuberculous disease of joints, minor operations, emergencies, treatment before and after operation, and anaesthesia. Students can read with profit the chapters on case-taking, bandaging, massage, bruises, and sprains. Chapters of general information include medico-legal notes, hints on *post-mortem* examinations, on hospital economy, on cutting fresh sections, on trusses and artificial limbs, and on making casts. Where treatment is mentioned actual prescriptions are given, as well as the composition of the various reagents used for special tests.

We can thoroughly recommend this book, and feel sure that it deserves an introduction beyond the portals of Edinburgh University.

TEXTBOOKS OF HISTOLOGY.

DR. A. McL. WATSON'S *Handbook of Histology*[3] may be recommended to students who are commencing the practical study of that subject. It is short, and confined to those matters which a student who is examining histological sections for the first time needs to understand. The author has apparently aimed at the greatest possible conciseness compatible with full and clear histological definition. The general plan adopted is to explain the structure of the organ by proceeding from its macroscopical to its microscopical features; from the conception thus gained the student should, without difficulty, be able to interpret his sections. The book should prove a useful and trustworthy companion in practical work.

A different standpoint is taken by Dr. H. E. JORDAN in his *Textbook of Histology*,[4] which has reached its fourth edition, and may therefore be considered to have established its reputation. The aim of the work is to present the subject in such a way as to awaken a more lively interest than is afforded by bare histological details, by associating the descriptions with considerations of practical import. With this object the subject is approached largely from the point of view of function, the known or believed function of the organ being first described, and its microscopical structure correlated with this. The result is an interesting volume, and the interest is increased by the sections on embryology and references to comparative anatomy. The book is copiously illustrated with good figures.

Professor ANGELO RUFFINI'S pamphlet on embryological technique[5] deals with the well-known difficulties attending the microscopical examination of certain ova in the early stages of development, more especially those of amphibia. The good fixation of these has always proved a troublesome matter, and Professor Ruffini claims to have worked out a method by which these difficulties are satisfactorily surmounted. His ingenuity has also invented an exact method for the orientation of the ovum in the paraffin block, of preparing a paraffin mixture which will not deform the ovum in the process of embedding, and of spreading the sections on the slide in a manner to ensure uniformity in their dimensions. The accurate determination of the mode of formation of the blastodermic layers of the ovum depends largely on perfection of technique, and Professor Ruffini appears to have made a definite contribution towards the latter.

Professor P. BOUIN'S *Eléments d'Histologie*[6] is a fairly up-to-date compilation of what is known about the anatomy and physiology of cells. After several chapters dealing with the general morphology and function of "the cell," the author proceeds to the description of tissue cells in which differentiation of form is associated with specialization of function. The first volume, now under review, is concerned with the histology of the skeletal and muscular tissues, of the blood and haemopoietic organs, the lymphatic and vascular systems. The book is intended primarily for medical students, and it is claimed that only essential descriptions are given in the main text; but, although many details of structural and functional significance and physico-chemical interest (which, as yet, are not fully explained or accepted) are printed in smaller type, there still remains much interesting matter not directly related to histology, which tends to distract the reader, and would be better introduced into a separate volume. To each section of the subject are appended a concise and useful summary and a sufficient bibliography. The numerous illustrations are beautifully reproduced and add greatly to the value of this attractive book. The second volume, which is now in preparation, will be concerned with the histology of the organs of nutrition, digestion, respiration, excretion, nervous system, and organs of reproduction.

PLASTIC SURGERY OF THE ORBIT.

SOME two years ago Dr. EASTMAN SHEEHAN of New York published a book on the *Plastic Surgery of the Nose*, which was noticed in our issue of July 10th, 1926 (p. 64). He has followed that up with another handsome volume on *Plastic Surgery of the Orbit*.[7] It is a massive volume of nearly 350 pages, of fine large clear type, and profusely illustrated with line drawings in the text and coloured plates. There is a preface by the veteran Professor PIERRE SEBILEAU of the Faculty of Medicine of Paris, and the book is dedicated to Harold Delf Gillies, whose valuable work for disfigured soldiers at the Sidcup War Hospital is so well known.

In this new book Dr. Sheehan begins with the anatomy of the parts, insisting that there can be no success in such delicate operations without a full and intelligent appreciation of the tissues and structures concerned. True to his belief, he has devoted sixty pages, with a dozen figures and nine plates, to these matters. Next, the preparation of the skin of the patient is dealt with in the same minuteness of detail, for here again the author maintains with truth that if the slightest laxity is allowed in this matter there can be no success in securing fine, little-recognizable scars, free from thickenings and from that bugbear of the skin surgeon, keloid. The preparation of the skin must be commenced many days before the operation. Here the interested co-operation of the patient is valuable in securing, through repeated steaming and massage of the skin, that evacuation of the grease glands which is necessary for the action of a delicate and efficient antiseptic. Of iodine the author will have none, since it irritates if it does not burn the skin, and gives it a leathery consistency. The preparation of grafts, both mucous membrane and skin, is described with meticulous care, for material such as this is so precious that any waste is little short of criminal, and may jeopardize a promising operation, with discouragement of the patient. Thereon follow accounts of a series of considered plans for restoration of eyelids which have suffered damage of various kinds from wounds or disease. Many of these are old familiar friends to ophthalmic surgeons, that have been handed down and practised for generations. Some of the operations are of later date, particularly those which deal with the lacrymal sac, after West's and Totti's methods, and the operations for restoration of contracted eye sockets.

At the end of the work there are two appendixes. One dealing with anaesthesia, and written by Dr. I. W. Magill of the Westminster Hospital, is excellent in its terse brevity. The second, by the author of the book, is a scathing condemnation of the use of paraffin injections; he says that the evils of this practice are now so well known to surgeons that few if any practise it, but the method still has a considerable vogue among unqualified practitioners, to the great harm of those to whom they minister. With regard to reparative operations in general the author says that these are ever fresh in their variations, but by way of warning to the venturesome he adds: "The fact is that whoever engages in this constructive branch of surgery must feel that he is 'called' to the work."

TUBERCULOSIS IN CHILDREN.

FOR some years Dr. P. F. ARMAND-DELILLE has given frequent courses of lectures at various centres in Paris on the subject of tuberculosis in children, and now one such course has been taken down as the lecturer delivered it and published in a small booklet, entitled the principal clinical aspects of tuberculosis in children.[8] This presents a very good summary of modern Continental views on an important subject by a physician with wide experience both in France and elsewhere, and it should be studied carefully by all those interested. The general etiology is first discussed, with contagion stressed as the important factor in causation, followed by sections on tuberculosis of the tracheo-bronchial glands, on generalized tuberculosis, and

[7] *Plastic Surgery of the Orbit.* By J. Eastman Sheehan, M.D., F.A.C.S. With a preface by Pierre Sebileau. New York: The Macmillan Company: London: Macmillan and Co., Ltd. (Cr. 4to, xxv + 348; 191 figures, 11 plates. 52s. net.)

[8] *Les Principaux aspects cliniques de la tuberculose infantile.* Par Dr. P. F. Armand-Delille. Les Publications Médicales. Paris: N. Maloine. 1928. (5½ × 6, pp. 74, 5 fr.)

on tuberculosis in the various organs. An interesting section devoted to the "fever of tuberculization" is important, for it stresses the possibility of tuberculosis as a cause of obscure fever in children and discusses the differential diagnosis. In further lectures on treatment Dr. Armand-Delille deals with artificial pneumothorax, heliotherapy, and the preventive measures carried out by the "Œuvre Grancher," whereby healthy children are removed from tuberculous families. All these three methods deserve close study, and indeed the whole of Dr. Armand-Delille's remarks on this subject have a value for workers in other countries. An index would be a useful addition to this little book in future editions, and also some illustrations.

CHEMISTRY FOR STUDENTS.

SIMON and BASE'S *Manual of Chemistry*[9] is a textbook for students of medicine, pharmacy, and dentistry. The thirteenth edition now before us has been produced by Dr. KRANTZ, who is professor of pharmacy in the University of Maryland. Dr. Krantz's preface expresses the hope that the manual "will furnish to the student a clear presentation of the science, an intelligent discussion of those substances which are of interest to him and a trustworthy guide to his work in the laboratory." We have seen many books on chemistry written for students of the subjects named, and too many that fail to accomplish the objects here expressed. Their failure arises from the fact that they offer the student something to learn instead of something to understand. Krantz's work is not of that kind. It is prepared with intelligent endeavour to engage the student's interest; it not only achieves the desire above expressed, but is the most admirable volume of its kind that we have seen for a long time. It is not only a book for elementary students, but it is full of information valuable for reference after the period of academical study. No embarrassment is caused to the elementary student by this fact, because fundamental learning is distinguished in the text from supplementary information by different types of print. The choice of reactions for inclusion in the text has been most capably made with a view to effective representation of the typical characters and properties of elements and compounds, and we note with satisfaction the inclusion of many valuable tests that are not widely known. Such a book could only be produced by one who is a learned and experienced chemist. It is the kind of book to buy for a lifelong possession.

NOTES ON BOOKS.

Burdett's Hospitals and Charities[10] has always been welcome as a handy book of reference which depicts the progress of philanthropy and hospital management, and the thirty-ninth edition indicates how the problems are changing. It has been decided to publish henceforth an article at the beginning of each annual volume bringing the statistical sections into relation with the most recent developments in hospital work. In the issue for 1929 Captain J. E. Stone examines the present financial situation of the voluntary system, and considers the new sources of hospital income from patients' contributions, and the provision that has to be made for road accidents of all kinds and for middle-class patients. An appreciable enlargement of the section devoted to mental institutions has enhanced definitely the practical value of the book, and more information is now given about King Edward VII's Welsh National Memorial Association. The most generally useful section is the concise directory of medical and educational institutions, philanthropical societies, and the similar organizations controlled by the London County Council and the Metropolitan Asylums Board. New entries include accounts of the aims and organization of the Merseyside Hospital Council, the blood transfusion service of the British Red Cross, and the Liverpool Hospital for Diseases of the Heart—the only institution of the kind outside London—and a note on recent administrative changes affecting hospitals in the Transvaal Province. Throughout the book every effort has been made to bring the information completely up to date; the index is good, and this year's edition may justly claim to be an improvement upon the best of its predecessors.

With the issue of a second edition of the *Manual of Hygiene and Public Health*,[11] by Dr. JAHAR LAL DAS, officiating assistant director of public health in the province of Bihar and Orissa, opportunity has been taken to revise the text and to add several new appendixes. This textbook, written from the standpoint of Indian life, is intended to meet the needs of public health officials and students in India, and deals more particularly with conditions incidental to tropical life. The first edition was reviewed in these columns two years ago.

The fifty-first volume of the *Transactions of the Medical Society of London*[12] includes the papers communicated at its meetings during the 155th session, from October, 1927, to May, 1928. Among these are the presidential address on "Surgery in the early days of the Medical Society of London," given by Mr. H. W. Carson, F.R.C.S., in October, 1927, the Lettsomian Lectures on "Rheumatic heart disease in children" by Dr. F. J. Poynton, the Lloyd Roberts Lecture on "The criminal law and insanity" by Lord Hewart, and the society's annual oration on "The lessons of rare maladies" by Sir Archibald Garrod. Most of the papers and discussions now published in full in the *Transactions* were reported at the time in our columns.

Volume xlviii of the *Transactions of the Edinburgh Obstetrical Society*[13] contains the papers read during the session 1927–28, many of which have been reported in these columns from time to time. Among the papers included is the valedictory address on "The preventive frame of mind in obstetrics" given by Professor R. W. Johnstone on relinquishing office as president.

Reprints of the various papers, memoranda, etc., contributed by the members of the staff of the Middlesex Hospital Medical School during the session 1927–28 to various British and American medical and scientific periodicals have now been collected and bound together in volume form.[14]

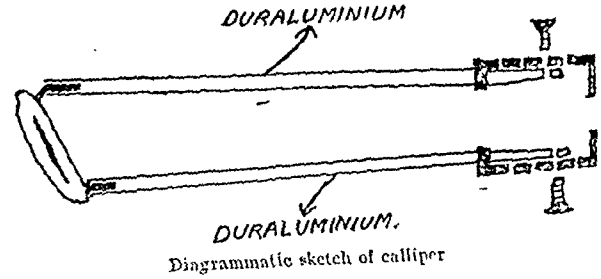
PREPARATIONS AND APPLIANCES.

A LIGHT TUBULAR CALLIPER.

MAJOR MEURICE SINCLAIR, C.M.G., R.A.M.C.(ret.) (London), writes: Whenever the weight-bearing function of a lower limb in an adult has to be suspended for any cause, and it is desired to permit the patient to walk with the aid of a Thomas calliper splint, the instrument shown in the accompanying diagram will be found advantageous. In it I have adhered to all the original principles, and have substituted side bars with duraluminium tubing; these are made for my patients by the Surgical Supply Depot, 23, Upper Phillimore Place, Kensington, W.8, and have been very satisfactory on account of their



Diagrammatic sketch of calliper

extreme lightness and comparative cheapness (45s.), and are every bit as solid. The comparative weights of callipers of similar sizes are interesting. One made with 3 8-inch round iron throughout was 3¾ lb., while the other, manufactured with tubing, was only 2 lb. The part of the tubular one which weighs the heaviest is the ring; so the patient not only derives great benefit from the loss of 1¾ lb. dead weight, but at once observes the lessened resistance to leverage in bringing forward the leg more easily. The gratitude expressed by the wearers has been so encouraging that I am anxious to submit the idea to the profession.

British Medical Journal.

SATURDAY, JANUARY 19TH, 1929.

MATERNAL MORTALITY INVESTIGATIONS.

NEARLY a year ago the Ministry of Health initiated a scheme for the investigation by local health authorities of the causes of puerperal deaths, and appointed a departmental committee to lay down the form and method of investigation and correlate the returns. This system of inquiry had been recommended by the Scottish Departmental Committee on Puerperal Morbidity and Mortality that reported in 1924, but had been anticipated in 1917 by Professor Matthew Hay, then medical officer of health for Aberdeen, who, with the concurrence of the local medical profession, at once put his scheme into action in that city. The result of its working during the ten years 1918–27 has now been published as a report to the Scottish Board of Health by Professor Hay's successor and his staff.[1] The Aberdeen report, therefore, calls for special attention and critical review, because it is the first of its kind and will give an impression of the results that may be obtained from this type of inquiry, and possibly also influence the form and fashion of subsequent reports from other areas.

During the ten-year period there were 252 deaths —a number, as the authors of the report state, "too small to permit of final conclusions," and only allowing of "*certain tentative deductions which the trend of* evidence would appear to warrant." Many interesting figures are given, such as the death rates at first and subsequent labours, and the influence of various personal factors—such as occupation, habits, and illegitimacy—for the most part confirming what was already known. The absence of any relationship between environmental conditions and maternal mortality is shown, the death rate in confinements in one-roomed houses being less than half that in those of four rooms and over. The death rates in the practices of midwives, medical practitioners, and institutions are compared, transferred cases being put back to the original attendant, and the mortality is found to work out at 2.3 per 1,000 deliveries for midwives, 5.6 for institutional outdoor practice, 6.9 for doctors, and 14.9 for institutional indoor practice.

There is a regrettable tendency, in the interpretation of these figures, to jump to conclusions from inadequate data. Among the midwives' cases the forceps rate was 5.8 per cent., and among the 445 cases in which the forceps were used there were no deaths. "The available evidence suggests, therefore, that so far as the midwife cases are concerned the application of the forceps has no prejudicial effect." Here the death rate is the only criterion, and no account is taken of morbidity, trauma, or recovery after invalidism with possibly permanent disability. On this principle the inference might equally well be drawn from the figures we have quoted earlier that if all the confinements in Aberdeen were conducted in one-roomed houses the maternal mortality would be halved. Then a little later we find: "It may be argued that in midwife cases there is no improper use of forceps, labour generally being advanced and dilatation commonly complete before the doctor is required to intervene, and that it is the improper use of forceps with the object of accelerating delivery that is responsible for trauma with ensuing sepsis in the practice of doctors." This assumption has truth enough in it to be accepted as a rough generalization, but it gives a wrong impression by its disregard of the conditions of medical midwifery practice. Responsibility for the "improper" use of forceps appears to be laid entirely upon the doctor, and no mention is made of the insistent pressure of the patient and her relatives on him to shorten her time of trial. Their demands may be irresistible if he is to retain his clientele. Often the sole reason for his being engaged is to secure anaesthesia, with its consequent slowing of the processes of labour, and the relief that his forceps brings.

The indoor institutional figures undoubtedly call for improvement, and in discussing the reasons for the high mortality emphasis is laid on spray or droplet infection from carriers, especially in overcrowded wards. The throat-carrier origin of streptococcal infection is accepted whole-heartedly by these observers, and colours their attitude towards puerperal infection. "Doctors, from the nature of their work, are of necessity repeatedly exposed to spray or droplet streptococcal infection, and may reasonably be assumed to have developed the degree of immunity which is necessary to the true carrier condition"—hence, it is argued, the higher incidence of puerperal sepsis in their practice. The principal suggestions made for lowering maternal mortality are the improvement and expansion of the ante-natal services, and the development of a new midwifery organization in which midwives conduct all normal deliveries while doctors provide the ante-natal services and deal with obstetrical complications. How the doctor is to be a sound practitioner of midwifery without a wide experience of normal cases is not precisely indicated.

In endeavouring to appraise the value of this very thorough investigation of ten years' puerperal deaths we may accept unhesitatingly its benefit to the locality. The collection of information of this kind is bound to tighten the strings wherever slackening is noticed—as, for example, in the high institutional death rate in Aberdeen. When adopted widely such critical surveys must tend to level up backward areas. We venture to express the hope, however, that in issuing similar reports, which are abstracted in the public press and are readily available to an uninstructed public, greater care will be taken in drawing, from small numbers and scanty data, inferences that may be open to misconstruction by those without knowledge of all the factors involved. Dr. T. F. Dewar, in his prefatory note to the report, clearly anticipates criticism of this kind directed against what he terms "tentative or provisional inferences." Nevertheless, all must agree with him that the Aberdeen inquiry has served an important purpose by "exciting a renewed interest among an extended circle upon a subject that every public health worker and good citizen must have deeply at heart."

[1] Report on Maternal Mortality in Aberdeen, 1918–27, with Special Reference to Puerperal Sepsis. 1928. H.M. Stationery Office. Price 1s. A summary of this report, from a correspondent in Scotland, appeared in the *British Medical Journal* of January 12th (p. 78).

PYORRHOEA ALVEOLARIS.

FOR years the problem of pyorrhoea alveolaris has been the battle-ground of investigators; and if it be true that doubt is the life-blood of progress the problem should be fast nearing a solution. Every pronouncement on this disease has inspired some sceptic with a diametrically opposed opinion. There are those who doubt its very existence; what we see, they maintain, is not disease, merely dirt. Others wish simply to change its name, which, by suggesting the presence of pus, may indeed serve to divert attention from the early

and less obtrusive stages of the disease. Views as to its etiology are no less varied and conflicting. There are those who maintain that pyorrhoea alveolaris is of constitutional origin: in the middle-aged to be ascribed to an arterio-sclerotic tendency, to a defect inherent in a "terminal circulation," or to premature old age of the alveolar structures; in younger persons to endocrine disturbances and vitamin deficiency. Others hold that it is a local disease of bacterial origin, beginning at the gum edge and attacking the constitutionally healthy and unhealthy alike. Some maintain, and others deny, that pyorrhoea and dental caries are mutually antagonistic. Bacteriologists are in a no happier plight. Every germ that has been held responsible has been acquitted by some sceptic or other. Even the histologists can find no measure of agreement. "Osteitis fibrosa," says one group; "Chronic inflammation," replies another; "Neither of these," maintains yet a third. Some clinical observers profess to classify their cases as true pyorrhoea, dirt pyorrhoea, pyorrhoea due to traumatic occlusion, and so forth. Others are content to avow that they cannot identify such groups. Is the disease curable or incurable? Are its effects serious or negligible? Even to these questions clinicians give the most diverse and conflicting replies.

How is the ordinary practitioner to create order out of this chaos and to harmonize the evidence supplied by his own experience? In his practice he sees pyorrhoea—real pyorrhoea with pus formation—in the young and the old, in the healthy and the unhealthy, in foul mouths and in mouths he would pass as clean. He knows that the disease can be cured by wholesale extraction of teeth, so is inclined to subscribe to the theory of a local origin. All cures short of extraction commonly fail him, and local cleanliness, which some tell him is effective both in prophylaxis and cure, he believes to be unattainable. Again, though in any particular patient he may not be certain that pyorrhoea is responsible for remote disease, he has seen enough to know that extraction is often an invaluable remedy. What can those who combine clinical and pathological experience do to resolve these doubts? An attempt is made by Mr. Humphrey F. Humphreys in a paper we publish this week at page 99. Mr. Humphreys differentiates between predisposing and exciting causes of pyorrhoea alveolaris, and among the former he cites the transitory nature of teeth and their supporting structures, and biochemical changes in calcium metabolism probably due to endocrine disturbances. Whatever may be said on behalf of the first of these causes—and explanations of pathological phenomena based on a consideration of evolutionary history are generally to be taken with some reserve—most of us, until there is further proof, would be inclined to share Mr. Humphreys's own scepticism about the second. But it is into his theory of the exciting causes that we would wish to follow him more closely. The *Leptothrix buccalis*, he maintains, acting jointly with oral secretions stagnant in the intradental spaces, produces a deposition of calculus, and thus is set up a vicious circle of irritation, pocket formation, secondary infection, and further stagnation. This description of an apparently logical sequence of events would appear, however, to need some qualification. If by oral secretion the author means normal saliva it is difficult to follow him. Mucus may stagnate, but hardly normal saliva, which, from whatever source, is always fluid. Nor can one accept, without some saving clauses, Mr. Humphreys's presentation of the part played by *Leptothrix buccalis* and calculus in the production of pyorrhoea. Does he use "calculus" and "tartar" as interchangeable terms? If so, does he differentiate between subgingival (serumal or black) tartar, which forms very slowly and is always deposited under the gum edge in masses cut off from the rest of the buccal cavity, and ordinary light-coloured tartar, which forms in large masses on any unrubbed intrabuccal portion of a tooth? Mr. J. G. Turner a few years ago showed that, whereas subgingival tartar always produces on culture a pure growth of *Leptothrix buccalis*, light-coloured tartar produces a growth of various organisms, but free from leptothrix. If, then, Mr. Humphreys by calculus means subgingival tartar, his theory as to the part played by *Leptothrix buccalis* would appear to be well founded; but if he means ordinary light-coloured tartar, or both forms of tartar, we think he is not in so strong a position. But once the leptothrix is inculpated is it necessary to suggest the complicity of oral stagnation? May not the *Leptothrix buccalis*, safely established in a periodontal sulcus and cut off from the buccal cavity and its secretions, get its supply of tartar-forming lime salts from blood serum exuded by the slightly irritated gums?

We feel that Mr. Humphreys in his general argument has gone to the root of the problem of the etiology of pyorrhoea alveolaris. His stimulating and provocative paper has moved us to make these criticisms on points of detail in the hope that useful discussion may follow on what we believe to be an important problem.

SOME EDUCATION PROBLEMS.

THE early days of each calendar year, during the Christmas vacation of the schools, witness a large number of education conferences. Owing mainly to a lack of co-ordination and an absence of direction to specific problems, the results of these gatherings are invariably disappointing. Their output is miscellaneous and indigestible. The work of some of these conferences is negligible, but that of others is often important, and an attempt to use these as a gauge of the trend of educational thought in certain circles, though difficult, is not without its value. During the present month the more influential of these pronouncements and discussions have been those concerned with the need for a closer co-operation between our educational system and the industrial and commercial life of the nation, the place of examinations in that educational system, and the importance of biology as a subject in the curriculum of secondary schools and universities or university colleges.

The first of these subjects was the main theme of Lord Londonderry's presidential address to the North of England Education Conference. It is, of course, a subject of the first importance, but not one which can profitably be discussed in any detail in this place. It is, however, some comfort to note the opinion of a responsible member of the present Government that "nothing could be more fatal to the country than that we should lose ground as an educated people under the stress of industrial and trade depression," and that "the chief guarantee of the future of our children is the undiminished provision of the means of education." A more immediate and practical application of these sentiments by the President of the Board of Education would be widely welcomed.

The second subject, that of the proper place of examinations, is of more direct interest to the medical profession, both because such tests are a necessary part of the course leading to professional qualification, and because medical practitioners in their daily work are becoming more and more aware of the deleterious

effects which the dread of examination, or the shrinking from an impending, even though not immediate, test of this nature, may have on certain types of children. In the medical course examinations must necessarily be a test of knowledge. This is no doubt true also of the general school and matriculation examinations; but the earlier we go back in the school course the more such tests should be directed towards the gauging of intelligence rather than knowledge, and this has, in fact, been recognized in such examinations of recent years. Moreover, factors other than examination results are now often taken into account in forming a judgement; but it remains true that the present compulsion to submit whole classes of pupils, rather than selected individuals, to severe external examination tests, and the growing tendency among many employers to regard success in such tests as a criterion of suitability for employment, may be in practice both dangerous and unjust. Sir Michael Sadler dealt with this subject fully in addressing the New Education Fellowship. He drew attention to a type of English folk, often refined, alert, scientific in their observation, and just in their moral judgement, who cannot reduce the operations of their minds to the currency of words; and very effectively said: "So long as most of the boys and girls of this primitive English sort could pass through childhood and youth unworried by examinations it did not matter that children of the other sort enjoyed the stimulus and reward of the examined life. But now that we are trying to sweep all English children into the net of secondary education it has become necessary to protect the interests of both sorts. The time is near when every little English child that comes into the world alive will, if it grows up, pass under the harrow of examinations. At present the harrow is blunt. But the spikes will get sharper." The reality of this danger may well be emphasized from the medical side also.

The third subject, the place of biology in an educational curriculum, is becoming yearly of more urgent importance. In general it is evident that the opportunity and the demand for biological experts in various capacities throughout the Empire is far greater than the supply; and it is at least highly probable that the number of those who cultivate this subject in institutions of university rank would be appreciably increased if it obtained a place, in an elementary form, in the curriculum of many secondary schools. The same is true of medical education. This matter was referred to at the Conference of Headmasters. Some rather wild remarks were made about the attitude of the General Medical Council, and, though it is clear that if headmasters were submitted to an examination on the character and functions of that Council they would almost all fail to pass, it may be agreed that with regard to making biology a pre-registration subject the General Medical Council moves with extreme slowness and a superabundant caution. In view of the movement for a lengthening of school education, now generally accepted except by Lord Eustace Percy, and for the completion of a full secondary school course for a large number of pupils, it would seem to be not untimely to give long notice that, as from some definite year, the age for registration as a medical student would be raised to 18 years, and that some knowledge of elementary biology would be required before registration. The Education Committee of the Council has merely raised the question in a very tentative form. In this connexion it may be well to direct attention to the need for further definition of the standard required in the preliminary scientific subjects in general, and to the short discussion in the November session of the General Medical Council raised by Mr. Monsarrat on behalf of the University of Liverpool, and by Dr. Brackenbury from the point of view of secondary schools, and reported in the *Supplement* of December 8th last (p. 245).

POTT'S FRACTURE.

ABOUT a hundred years ago that great authority Dupuytren, with all his skill and experience, felt compelled to admit that even under the most favourable conditions fractures at the ankle almost always resulted in deformity and lameness which rendered progress difficult or painful. It must be admitted that until comparatively recent times this statement remained true, as was shown by the statistics as to the Metropolitan Police published by the late Mr. Clinton Dent. But there are good grounds for the belief that very much better results are now generally obtained, thanks to the teaching of surgeons such as Sir Robert Jones and Mr. Harry Platt. Against Dupuytren's depressing prognosis may be set the dictum of Sir Robert Jones that such injuries are easy to treat if certain principles are borne in mind and followed. Recently Dr. Frank Dickson of Kansas City read an instructive and lucid paper on fractures of the ankle before the Section of Surgery, General and Abdominal, at the seventy-ninth annual session of the American Medical Association.[1] He quoted Ashurst's figures of 300 cases, and agrees with his and Platt's conclusion that Pott's fractures (abduction and external rotation) form over 80 per cent. of fractures of the ankle. The greater part of the remaining 15 to 20 per cent. are inversion fractures, which are easier to treat and less disabling ultimately. Dr. Dickson's description of the various forms of fracture of the lower ends of the leg bones and of their treatment is clear, and it is well illustrated by *x*-ray pictures. He recommends immediate reduction and the application of plaster-of-Paris, which is at once divided on each side so as to form a bivalve splint; this can be removed to permit inspection of the ankle, and, if necessary, to allow for oedema of the soft parts. In these, as in all other actual or suspected fractures, *x*-ray examination and the recording of its results is a *sine qua non*. There should be no exception to the rule that, when possible, two plates—lateral and antero-posterior—should be used, for in some cases the bone injury and displacement may be invisible from one direction, though obvious from another. We would add, too, that it is a great advantage in dubious cases to be able to compare the radiograph of the injured limb with one taken of the sound limb. From the point of view of restoration of function, it has been shown by various authorities that the broken fibula is of small importance in comparison with the concomitant displacement of the astragalus and damage to the ankle-joint. The surgeon must remember that the displacement of the astragalus is generally twofold, as radiographs will show him; it is tilted and displaced outwards, and it is also displaced backwards. As a rule the lateral displacement is easily recognized, even without the help of a radiograph, and is not likely to escape correction; backward displacement, however, is less obvious, and too often it is not properly corrected, in which case the range of dorsiflexion is more or less reduced and the disability may be permanent, unless it is corrected by a secondary operation. In these injuries the form of splint or nature of the retentive apparatus used is of minor importance so long as reduction of the deformity is complete in the first instance, which fact can be demonstrated by the entire restoration of the normal dorsiflexion movement in the ankle-joint proper, exclusive of movements of the tarsal articulations. The normal astragalo-tibio-fibular articulation is a remarkably rigid mechanism, allowing only of angular movement

[1] *Journ. Amer. Med. Ass.c.*, vol. 91, No. 12, p. 855.

in the sagittal plane—that of flexion and extension—a fact which is almost completely masked by the extensive rotatory, abduction, and adduction movements immediately below it. In the event of the ankle mortise being in any way deranged the incidence of the body weight and of shocks transmitted upwards through the foot is altered prejudicially; pain and secondary osteo-arthritis follow, no matter how much the displacement may be masked by adaptation of the position of the subastragaloid portion of the foot.

NOTIFICATION AND CONTROL OF VENEREAL DISEASE.

AT a general meeting of the Society of Medical Officers of Health held in November last there was a very interesting discussion on the advisability of adopting compulsory methods in relation to any schemes in operation for dealing with venereal diseases. The three introductory papers, written from entirely different points of view, were read by Dr. A. K. Chalmers, Dr. R. A. Lyster, and Dr. William Robertson, the medical officer of health for Edinburgh. These papers, together with a report of the discussion which followed, are printed in this month's *Public Health*. It will be remembered that at the meeting of the Representative Body of the British Medical Association at Cardiff in July last a motion was proposed on behalf of the Edinburgh and Leith Division favouring compulsion "in order to secure continuance under treatment until discharged by a registered medical practitioner," and an amendment was moved by Mr. E. B. Turner in favour of the exercise of such compulsion by local option. Both amendment and motion were negatived by large majorities. The discussion was fully reported in our *Supplement* of August 4th, 1928 (p. 64). These reports may well be read in conjunction, for their subject is both important and difficult, and it is bound to come up for reconsideration from time to time. It may be recalled that a bill to give certain powers to apply compulsion to persons requiring treatment for venereal diseases was promoted by Edinburgh Corporation as a private measure last session, and was refused a second reading, after a prolonged debate, by 156 votes to 93, in the House of Commons on April 19th. Glasgow Corporation, about the same time, approved a draft bill of an even more drastic nature; a summary of its provisions was given in our issue of April 28th, 1928 (p. 727). It is therefore evident that the advocates of compulsion are strong in at least certain quarters in Scotland, and are unlikely to let matters rest. Nevertheless, there can be little doubt that the general body of medical opinion, as of public opinion, in this country will be with Dr. Chalmers rather than with Dr. William Robertson. Liberty is, fortunately, very dear to the English mind. Never in this country has compulsory submission to a particular form of medical treatment been imposed on a subject. There is compulsory confinement, under proper conditions and with very elaborate safeguards, of individuals suffering from some forms of mental disease who are unable to exercise volition of their own. There may be compulsory isolation (but not compulsory treatment necessarily) of persons suffering from certain forms of infectious disease of short and relatively definite duration. There is in certain cases compulsion on parents or guardians to see that proper treatment is secured for children who are unable to protect themselves. Beyond this, however, English law has not gone, and it is quite unlikely that public opinion will tolerate any greater element of compulsion in the sphere of venereal disease. Dr. Robertson is, of course, right when he says that "every medical officer of health knows that the liberty of the subject doctrine, if literally interpreted, would spell ruin to many of the activities directed at prevention," but he thereby begs the question. He is no doubt correct, too, when he says that the present position "is galling to the administrative officer," and that his "highly qualified lady almoner" was "disheartened and worn out" because she could not threaten defaulters with legal pains and penalties as well as physical ones. But English law has objects other than an unconditioned support of the laudable zeal of administrative officers, medical or other. Moreover, it has yet to be shown that there are any detailed administrative methods of enforcing continued treatment that would be effective in practice. The difficulties between a private practitioner and his patient might be immense, and, as one of the speakers in the discussion said, "until a recognized amount of treatment was decided upon by the profession it would simply be a question of luck whether an individual received a certificate in a fortnight or in ten years." Further, Dr. Lyster seems undoubtedly right in logic when he points out that if the arguments for compulsion be valid there might as well be compulsion to prevent, which is relatively easy, rather than to cure, which is often very difficult. As a matter of fact, the measure of success in the campaign against venereal disease already attained is not unsatisfactory, though imperfect in some 25 per cent. of the cases. The position is well set out by Dr. Chalmers in the one discussion, and by Mr. Bishop Harman in the other. There must certainly be a continuance of the present campaign of education and propaganda. There should be an increase in the facilities for obtaining skilled and continuous treatment in any localities where this is not now available or adequate, for it is the lack of these facilities which sometimes leads to discontinuance of treatment. The one direction in which it seems possible to adopt further measures is in the protection of infancy and childhood. Where a child has been born suffering from the effects of venereal disease in the parents it would be within the limits of present public policy to take measures, involving a degree of compulsion, to protect any future offspring, and the Society of Medical Officers of Health certainly came to a wise conclusion when, in the end, it resolved "to consider whether any scheme of action can be recommended in reference to the parents of children infected with venereal diseases."

HEALTH SERVICES IN IRAQ.

THE building up of the new kingdom of Iraq since 1921 has been followed with sympathetic interest in Great Britain, partly because the State owed its existence largely to the ultimate success of the forces of the Empire in the Mesopotamian campaigns, and partly because of the romance attaching to the land which includes within its boundaries Baghdad and Nineveh. In the constructive work undertaken since the establishment of the State British doctors and officials have played a considerable part, and it is interesting to learn from the report for 1925 and 1926 of the British inspector-general of health services in Iraq that, in spite of many difficulties, appreciable progress has been made in the sphere of medicine in this period. Five or six years ago the attitude of the Government towards health services was unsatisfactory, the policy being to undertake the minimum degree of responsibility in regard, for example, to the provision of hospitals, and to leave this task largely to the impoverished local authorities. Later, however, a more enlightened view gained acceptance, and in the end the Government admitted financial responsibility for all medical institutions. In recent years the main obstacles to the development of health services have been lack of funds and the difficulty of securing suitable recruits for the staff. These two factors are closely associated, and the conditions of service for local medical officers leave room for improvement. The inspector-general, Major T. J. Halliman, takes occasion, however, to congratulate the service on possessing a solid nucleus of competent and conscientious Iraqui doctors, who have been with it from its

commencement. Valuable work has also been done by subordinate medical personnel, notably pharmacists and dressers; several pharmacists have been given special training in hospital out-patient departments before taking charge of dispensaries for which it has been impossible to obtain doctors. The shortage of State-provided hospital accommodation is accentuated by the fact that charitable institutions, although efficient where they exist, are few in number in Iraq. In the hospitals administered by the health service there were during 1926 1,190 beds, an increase of only 20 over the number of beds provided in 1924. Several additional institutions were, however, under construction, but much more extensive works are required before the hospital provision can be regarded as adequate. Schemes for the doubling of the bed accommodation at the Royal Hospital at Baghdad, and for the rebuilding of the Mosul Civil Hospital, have been submitted to the Government. Steady progress has been made in the establishment of dispensaries in the smaller towns; ten new dispensaries were opened in 1925, and ten in 1926. While deficiencies in personnel and equipment have prevented the full development of the service in the way desired by those responsible for its conduct, their efforts have been rewarded by a gratifying access of esteem in the eyes of the public, whose appreciation is reflected in the figures of attendance at the Government hospitals and dispensaries: in-patients numbered 18,756 in 1926, as against 15,632 in 1923, while the number of new out-patients rose from 835,904 in 1923 to 1,610,445 in 1926. Had facilities been available there is no doubt that the rise in the number of in-patients would have been much greater, and it seems certain that as the public demand for medical treatment becomes more extensive and insistent the Legislature will be obliged to find means of increasing the resources of the health service. Major Hallinan, in his introduction, points out that the success of any of the projects for the agricultural development by large irrigation schemes depends on a sufficiency of population to exploit the areas so gained, and that the existing population barely suffices for present labour requirements. He urges, therefore, the importance of conserving the country's potential human resources by adequate health measures—directed notably to the reduction of child mortality—and suggests that it is a matter for careful consideration by the Iraq Government whether the present rate of progress in the health service should only be maintained, or whether it would not be more advantageous, for economic reasons, to develop it at a greater rate than other departments.

BAYLISS-STARLING MEMORIAL.

THE appeal for subscriptions to a memorial to the late Professors Sir William M. Bayliss and Ernest H. Starling has up to the present resulted in a sum which, with interest, will amount to over £2,600. The sum has been contributed principally by personal friends, relations, and pupils of the two distinguished physiologists, but very liberal subscriptions have also been received from their admirers in America, various European countries—principally Germany—from learned societies, and from various physiologists and members of the medical profession in all parts of the world. The committee which has been concerned with the memorial fund considers that the objects outlined in the printed appeal have been achieved. A small part of the fund has been employed for the provision of a simple memorial tablet, designed by Professor A. E. Richardson, F.R.I.B.A., which will be erected in the entrance hall of the department of physiology and biochemistry, where it will occupy a suitable place over the bust of Sharpey. A material memorial or an annual lecture would, however, have been less acceptable to Bayliss and Starling than the provision of means whereby young workers of suitable training and ability might be attracted into these fields of study. The bulk of the sum, therefore, will be used for the creation at University College, London, of a Bayliss and Starling studentship, which will be open to a graduate or undergraduate in medicine or science of suitable standing to enable him to spend a year or more in such training in physiology and biochemistry as would fit him for research. For this purpose the sum of £2,500 will shortly be transferred to the University of London to be held in trust for the creation of such a studentship. A further sum will be added to this when the cost of the tablet and other small expenses have been covered. The Governing Body of University College has agreed to assist this scholarship in a very material way by remitting all fees for instruction and ordinary expenses payable by the selected candidate, and, further, it is hoped that it will be possible to make the first award of the scholarship in June of the present year.

SKIN CANCER IN AUSTRALIA.

EVEN sunshine may not be an unmixed blessing, and for some time it has been thought that the unenviable frequency of various forms of malignant disease of the skin in Australia is due to the abundance and peculiarly vivid power of the sun's rays enjoyed on that continent. Several Australian dermatologists, notably Molesworth and Paul, have called attention to the importance of this factor in producing rodent ulcer and epithelioma of the skin, and Dr. Herman Lawrence[1] has analysed the cases occurring in his own practice during a period of twenty years. He finds that during that time there has been a steady increase of rodent ulcers and keratoses (so often the pre-malignant stage of skin cancer). He distinguishes keratoses, rodent ulcer (perhaps better termed basal-celled epithelioma), and squamous-celled epithelioma as the epithelial triad. Now there are other countries where the sun shines just as strongly as it does in Australia, but which do not suffer to anything like the same extent from the epithelial triad. What, then, is the cause of this unfortunate pre-eminence? Dr. Lawrence suggests two reasons. In the first place, other countries where the sun's power is so manifest are chiefly inhabited by the pigmented races of mankind, who find in their darker skins the natural protection against the pathogenic properties of sunlight. Secondly, in Australia not only is there abundant sunshine, but the humidity of the atmosphere is remarkably low. In many regions in Australia the humidity is half that in southern England, while there are twice as many hours of sunshine a month. The importance of this lies in the fact that moisture in the air is a powerful absorbent of the ultra-violet rays. The irritant qualities of these rays have, of course, long been known, and it has been suspected that they were the chief factor in producing Dr. Lawrence's epithelial triad. Unexpected confirmation of this theory has been obtained by him from the case of a young man, aged only 27, who had undergone treatment by ultra-violet rays consisting of half-hour exposures of both the front and back twice a week for over a year and a half! The consequence was the formation of numerous multiple keratoses. It is true that no epithelioma was produced, but, after all, the duration of this intensive ultra-violet radiation was comparatively short, whereas dwellers in the backblocks of Australia are exposed to excessive sunlight for a lifetime. Dr. Lawrence asks if it is possible to prevent the apparent increase of skin cancer cases in Australia. He suggests that blonde individuals who produce little or no pigmentation in response to light stimulation should be discouraged from outdoor work in low humidity areas of the continent. He points out that the French already refuse blonde applicants for Government service in hot climates, since they appear to have less

[1] *The Relative Low Humidity of the Atmosphere and Much Sunshine, as Causal Factor for the Great Prevalence of Skin Cancer in Australia.* By Herman Lawrence, M.R.C.P.Ed.

resistance to tropical diseases than darker men. Otherwise he can only recommend broad-brimmed hats for men and dark veils for women; for golfers and tennis players he suggests the use of ointments and powders containing quinine, which has a special power of absorbing ultra-violet rays to produce fluorescence. For the treatment of the epithelial triad when established he speaks enthusiastically of radium, but the chief difficulty is to persuade the patients to apply for aid sufficiently early. In Australia the help of the wireless has been enlisted for this purpose, and after a broadcast by one of the higher officers of the Commonwealth Health Department on cancer, in the course of which he indicated the importance of obtaining early advice about small warty-looking formations on the skin, a considerable number of persons came up for treatment with keratoses and early rodent ulcers.

POISONING BY METACETALDEHYDE TABLETS.

IN the current (December) issue of the *Archives of Disease in Childhood*[1] Dr. Reginald Miller describes two cases of poisoning in children by "meta fuel." This preparation, which appears to consist of metacetaldehyde, is supplied in the form of white tablets to take the place of methylated spirits for lamps and stoves. As might be anticipated, the tablets are occasionally mistaken for sweets by small children; the symptoms described by the author are those of acute poisoning of the central nervous system—namely, drowsiness and convulsions. In one of these cases, a boy aged 16, there was some albuminuria, while in the other, a child aged 4, the left leg was held rigid, the right being extended in the tetany position. These tablets, attractive in appearance, though hardly so in taste, may be left within the reach of small children, and the author considers that the public should realize their poisonous properties when swallowed. We have previously made some reference to the first of these two cases (see *Epitome*, 1927, vol. ii, para. 274). Metacetaldehyde is only slowly absorbed, and the treatment should, therefore, include gastric lavage and the administration of a purge.

PHRENOLOGY AND CRIME.

IN a recent lecture[2] Dr. W. Norwood East, Medical Inspector, H.M. Prisons, reviewed the attempts which have been and are being made to recognize and treat the born criminal by the application of scientific methods. A century ago Dr. George Combe maintained that every criminal should be examined phrenologically; if his or her organs of "combativeness," "destructiveness," or "acquisitiveness" were found to be developed to an exaggerated degree, while those of "benevolence" and "conscientiousness" were undersized, then the case required the special consideration of judge and jury. Phrenological methods proved to be useless. So, too, did the methods which sought to isolate a criminal type by a study of physiognomy. A similar fate has overtaken the Lombroso school of anthropologists, who held that born criminals were marked by developmental stigmata. The investigations undertaken by Dr. East's own service, the results of which were published by the late Dr. Charles Goring,[3] demonstrated that the criminals of England could not be distinguished from her law-abiding citizens by any means known to anthropologist or anatomist. Dr. East holds that the criminologists of to-day must look to psychology for scientific guidance, both for means of recognizing the pathological criminal and for just methods of treatment. He is not over-sanguine that psychology in its present state can give effective help. He sums up his attitude to psychology thus: "Intelligence tests devised by psychologists and educationists have done much in recent years to assist us in the diagnosis of the mental condition of delinquents. By their aid subnormal mental states have emerged clearly from the material with which they were surrounded and confused. We are not in so advantageous a position when dealing with temperamental defects, and further progress in the prevention of delinquency may result if reliable tests of temperament are resolved. But the criminologist must look again to the psychologist for help in grading temperamental defect, as this presents peculiar difficulties, inimical to accuracy if the subject has already offended against the law."

BRITISH EMPIRE CANCER CAMPAIGN.

THE MARQUESS OF READING presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on January 14th, when a number of grants were made, including a sum not exceeding £2,500 for cancer research work at St. Bartholomew's Hospital; £150 to Professor A. J. Clark, M.D., of Edinburgh for radiological research work; and a contribution of £100 towards statistical investigations being carried out by the Yorkshire Council of the Campaign. The Grand Council confirmed the recommendation that two prizes of £500 each, with an appropriate medal, should be offered in the years 1931 and 1933 respectively for the best original piece of work carried out in the British Empire on the investigation of cancer. The prizes will be known as the Garton prizes and medals, and the subjects will be chosen by the Investigation Committee of the Campaign. The competitors may be either single research workers or a team of scientists working together. The following were invited to become members of the Grand Council: Mr. Malcolm Donaldson, F.R.C.S., of St. Bartholomew's Hospital; Mr. R. G. Hogarth, F.R.C.S., of Nottingham; Major-General Sir Ernest Swinton, professor of military history at Oxford; and Mr. Cecil Rowntree, F.R.C.S., of the Cancer Hospital, London. Vacancies on the Scientific Advisory Committee were filled by nominations through the Royal Society—namely, Dr. Mervyn Gordon, F.R.S., consulting bacteriologist, St. Bartholomew's Hospital; Dr. J. C. Drummond, professor of biochemistry, University College, London; and Professor Sidney Russ, D.Sc., of the Middlesex Hospital.

THE HALF-YEARLY INDEXES.

THE usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been printed; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

THE KING'S ILLNESS.

WE understand that for the time being there is nothing of consequence to add to the information given in this column last week [illegible] authoritative medical statements p[illegible] 8th (p. 1051), December 15th (p. 1106), December 22nd (p. 1151), and January 5th (p. 31). The recent bulletins have all recorded quiet days; and comparing them with those issued earlier in the month we may infer, without undue optimism, that His Majesty has definitely gained ground. The outlook is more hopeful now than at any time in the past seven weeks.

THE MEDICAL USES OF RADIUM.

RECENT discussions on the use of radium in the treatment of cancer have served to emphasize the opposed attitudes of the general public and the medical profession towards new remedies for disease. During the past few months any person gaining his knowledge exclusively from the lay press might have been forgiven for concluding that radium had proved so certain a remedy against cancer that the only reasons for the continuance of surgical treatment in this disease were the shortage of radium supplies and the determination of surgeons to retain, at whatever cost to the public, a lucrative source of income. To form such a conclusion he would have required, indeed, no undue power of ratiocination; the actual statements have been made categorically and repeatedly in some of the most reputable organs of public opinion. The group mind reacting to a new therapeutic device appears to be governed by an "all or nothing" law—the device is either a panacea or it is valueless. The attitude of the medical profession by contrast has been one of scientific scepticism, which must not, however, be confounded with a mere sterile agnosticism.

If any indisputable fact has emerged from the scientific discussions on the value of radium, as contrasted with those animated by propagandist zeal, it is that there are not yet sufficient facts on which any final conclusion may be based. Admittedly there exists, in addition, some evidence suggesting that radium therapy may be proved superior to excisional surgery in the treatment of cancer in certain parts of the body, notably in the cervix uteri, the breast, the larynx, and the tongue. But it is well to bear in mind, as Mr. Victor Bonney pointed out in this *Journal* on December 8th, 1928 (p. 1064), that prognosis of cure involves an important time factor—in his view up to ten years—and that dogmatic pronouncements at this stage can be made only at the cost of scientific truth.

A favourite expedient of the popular propagandist in favour of radium therapy has been to compare the Continental and the British investigations, much to the disadvantage of the latter. The boundary method of limiting the spread of cancerous growths by surrounding them with needles containing radium has, for example, been described as a new technique emanating from the Continent, Brussels in particular. In point of fact, as Professor Joly of the Irish Radium Committee pointed out in our issue of January 5th (p. 42), the technique is not new, and it was evolved not on the Continent but in Dublin. Another popular writer has stated that whereas great progress has been made in Belgium and in Germany, "our record in this country, apart from following very slowly, may be described as *nil*." The value of such statements may perhaps be described with equal brevity. Ignorance is no excuse for those who presume to instruct the public, and incidentally to indict the scientific workers of a nation.

The papers recording work in radiotherapy by individual investigators and groups of investigators may perhaps be overlooked by those who do not regularly read the medical and scientific press and the journals of learned societies; but since 1922 a series of reports issued from the Stationery Office has made available for anyone who has cared to look for it a knowledge of systematized research in this country on the problems connected with radium therapy. The latest of these reports,[1] just issued, shows the record of work done with a stock of radium salt entrusted by His Majesty's Government to the Medical Research Council, and distributed by the Council on loan to various research centres. This report, as may be expected, is but poor reading for those who prefer final pronouncements to statistical data. No conclusions are drawn beyond those warranted by the available facts; though new methods have been developed no attempt is being made to evaluate them. The claims of any technique, it is pointed out, can be established only by a statistical inquiry after a sufficient period has elapsed since its adoption. Moreover, exploration of all the technical possibilities of radio-surgical access and of variations in dosage is essential before any final conclusion can be reached as to the value of radium in the treatment of cancer.

[1] Medical Uses of Radium. Summary of Reports from Research Centres for 1927. Medical Research Council, Special Report Series, No. 126. Price 1s. net.

PRESENT-DAY RADIOLOGICAL METHODS.

The reports from the various centres reveal a general tendency to use less intense radium foci, but with a corresponding prolongation of exposure time. Although the older practice of relying on short exposures from tubes containing as much as 20 or 30 milligrams of element still prevails in many centres for the treatment of certain cancers, notably of the cervix uteri, exposures for a week or more from tubes containing one or two milligrams are now relied upon in the treatment of cancer affecting the buccal cavity, vulva, and larynx. A similar technique has been adopted by the surgical unit of St. Bartholomew's Hospital in the treatment of a series of 27 cases of operable breast cancer. Thirteen of these cases have been apparently cured (though one died of intercurrent disease); local improvement was secured in 4, but the patients died of metastases; and 10 cases are believed to be improving. At the Middlesex Hospital, where radium therapy of breast cancer is used most frequently as supplementary to radical operation, tubes containing 10 to 20 milligrams of element are inserted into the intercostal spaces, supraclavicular fossa, and apex of the axilla, and are left in position for twenty-four hours. Visible recurrences are treated by a boundary method, which in a majority of cases appears to secure the disappearance of the local growth.

Cancer of the Cervix Uteri.

Cases of cancer of the cervix uteri are generally classified for statistical purposes into three groups—operable, borderline, and inoperable. A statistical survey is, however, complicated by the fact that some workers adopt only the first and last classification, while where all three are adopted there would probably be differences of opinion about the allocation of cases into the borderline group. Furthermore, there are degrees even of inoperability. A study of the data from the various research centres brings out the fact that whereas a considerable proportion of inoperable cases remain alive one or two years after radium treatment, this proportion is much smaller when the interval is three or four years. From this two separate conclusions may be drawn: either many cases now apparently well will recur within three or four years, or the technique has so far improved that the results really are better than those obtainable three or four years ago. Which of these conclusions is correct can be proved only after a sufficient time has elapsed. It is noteworthy that when treatment with radium is supplemented by means of *x* rays or by externally applied gamma rays, better results are obtained than when radium is employed alone. Probably results vary with the effective range of irradiation, though admittedly not with this factor alone. A patient with a purely localized growth, for example, treated by radium applied per vaginam may die of old age. One in whom the disease is a little further advanced may have just beyond the zone of effective action, a very early growth, which would continue to develop slowly in spite of complete cure of the disease in the vagina and cervix. Recurrence *in situ* occurs only very rarely. The disease is graded, and though technical advances may extend the limits of irradiation, at present diagnosis and treatment while the disease is strictly localized affords the best chance of complete recovery.

With increasing experience has grown up more detailed and more precise knowledge of the clinical phenomena associated with the use of radium therapy. Haemorrhage, it has been found, ceases in the vast majority of cases, though in some it returns shortly before death. In inoperable cases there is usually no difficulty in getting rid of the growth in the uterus, but growth tends to continue in the deeper tissues, causing strictures. Stricture may, however, be due to the laying down of ordinary fibrous tissue.

Pelvic and rectal pain, tenesmus, and blood and mucus from the rectum, characteristic of late radium reaction, may appear six to twelve months after irradiation. Such symptoms may pass after a week or two, or, if severe, may persist for several weeks. The associated pathological changes vary in intensity from a mere œdema to a considerable pelvic infiltration with deep rectal ulceration and vesical fistula. The clinical picture, indeed, may so far simulate recurrence of cancer, with rapid extension, that it is important to stress the undesirability of repeating the radiological treatment of these cases. Fortunately, in the majority, even when the reaction is intense, symptoms subside rapidly and the tissues regenerate; in some cases repair is slow. Attempts are being made to lessen the risk of injury to the superficial tissues, without, however, appreciably diminishing the distance dose, by cutting out some of the softer rays.

Mouth and Nasopharynx.

The various methods used in the radium treatment of cancer of the tongue differ from each other in points of detail, but there is a consensus of opinion that these growths respond much better when comparatively small quantities of radium are used and allowed to act for periods of from five to eleven days than when larger quantities are used for periods of twenty-four hours or less. In some centres radium treatment of the primary growth is followed some weeks later by the surgical removal of the glands of the neck, radium being put into the glandular region to deal with any residual growth; in some, after the initial treatment of the primary growth, surface applications of radium are made to the glands; in others, irradiation has been made by the simultaneous insertion of radium into the tongue and into the glands. Some workers insert radon seeds into the tissues by means of an introducer consisting of a hollow needle down which the seed is pushed by a stylet. The method is one especially adapted to outpatient practice, but suffers from the possible disadvantage that the filtration is inadequate, the reaction in mucous membranes is more severe than with needles, and the radon is rather concentrated. These difficulties appear, however, to have been overcome at St. Bartholomew's Hospital. A slow necrosis of the alveolus, due to the tubes being placed too near the bone, occasionally follows the irradiation of mouth cases. The condition can be prevented by taking care not to give too concentrated a dose near the bone. Radium and x-ray ulcerations have been successfully treated by syringing sloughs with normal saline solution, and then, when these have separated, packing the ulcer crater with saline-soaked cotton-wool.

Larynx and Œsophagus.

A majority of cases of intrinsic cancer respond favourably to radium treatment; but when the cancer has transgressed the boundaries of the larynx proper improvement is rare. Of four cases of intrinsic cancer treated at St. Bartholomew's Hospital only one failed to respond favourably; but only one case in five of extrinsic cancer showed signs of improvement. Growths of the œsophagus do not appear to be benefited by radium treatment; even when temporary improvement occurs it is followed only too often by speedy relapse. The treatment of these cases raises peculiar technical difficulties. Not only is the method of approach intricate, but it is often impossible to determine the length of œsophagus involved and the extent of the lateral growth.

Cancer of the Rectum.

A combined technique of operation and irradiation is generally used in the treatment of rectal cases. A preliminary colostomy is followed by exposure of the growth from behind, with temporary closure of the anus and removal of the coccyx. An average of 14 mg. are used for the glandular areas, and 30 to 50 for the growth, and if the patient can stand a maximum dose the radium is left in for such time, not exceeding 240 hours, as will bring it to approximately 10,000 milligram-hours. The results of treatment are not considered in the report, but the indications are that operable cases are at present more likely to benefit from surgical treatment than from treatment by radium.

Sarcoma and Lympho-sarcoma.

The response of sarcoma to treatment by irradiation appears to vary with the histological nature of the growth. Of 31 cases thus treated, 17 were apparently cured, and 8 relieved; the best results were obtained in the treatment of fibro-sarcoma, the worst in the treatment of lympho-sarcoma.

Nova et Vetera.

THE ORIGIN OF "QUARANTINE."

THE word "quarantine" is, of course, synonymous with, if not derived from, the French word "quarantaine," which merely means a group of forty—be it of days or of anything else. Its application to the detention of travellers or goods on a sea or land frontier, in the interests of public health, arose from the fact that such detention was most frequently one of forty days. Of the many uses of the word in non-medical matters little need be said here.* In its more modern application the origin of the word has been largely lost, and it has come to mean a detention of any duration, mostly on a frontier of some kind. But it has not infrequently in the past been applied also to the purely interior measure of shutting up infected persons and their families and dependants in their houses for a period of time. Defoe, in his semi-historical account of the Great Plague of London, repeatedly uses the word in this sense; and in one passage he speaks of a "demi-quarantine," as implying a detention of twenty or thirty days; and in another, of "not a quarantine of days only, but a soixantine—not only 40 days, but 60 days or longer."

A detention of some period or other, for the purposes of observation, is one of the oldest of public health measures. The seven days' isolation, outside the camp, of persons suspected of leprosy, required by the Mosaic law, was more or less of the nature of a quarantine.† At what era in history the period of forty days came to be chosen for such detention has not, it would seem, ever been clearly ascertained. It has, however, been asserted by at least one writer that a detention of forty days was first adopted during the great plague epidemic of the latter half of the sixth century, and that herein lies the true origin of the measure and of the word. The statement to this effect is so categorical, and, could it be confirmed, this early origin of a true "quarantine" would be of such interest and importance, that it has seemed worth while to follow the matter up and endeavour to search out the original authorities for the assertion. Unfortunately such endeavour has not been crowned with success.

The statement was first made in the following passage from a letter addressed, in 1819, to the then President of the Board of Trade and Treasurer to the Navy by Dr. A. B. Granville:‡

"The positive belief in contagion, and the consequent idea of seclusion as a means of preservation from it, can be traced to a much earlier epoch even than the Crusades; for we find both explicitly mentioned in the acts and edicts of some of the Oriental Emperors during the sixth century, issued with a view of preventing the propagation of the plague. It is there enjoined to those who come from a country known to be infected, to repair to a particular spot, there to be watched for the term of *forty days*, in order to ascertain whether they brought with them the seed of the disorder. Here then is the true origin of the word *quarantine* —and here we may place the date of the first enactment of quarantine laws, under the impression that the plague was contagious. So that these laws, far from being of the short standing of scarcely *three* centuries, reckon a succession of more than thirteen hundred years."†

* The "King's Quarantine" denoted a "truce of 40 days, appointed by St. Louis, during which it was expressly forbidden to take any revenge" (*Chambers's Cyclopædia*); while others define it as the forty days "allowed the friends or relations of a principal in a private war to grant or find a security" (*Murray's Dictionary*). In law the term "widow's quarantine" was given to the forty days during which a widow, entitled to a dower, had the right to remain in the chief mansion of her deceased husband" (ibid.). Robert Curzon, in his *Monasteries of the Levant*, speaks of "the Mountain of Quarantine, the scene of the forty days' temptation of our Saviour."

† Leviticus xiii. This isolation was analogous to, rather than identical with, a true quarantine; it was apparently a purely interior measure, applied to persons already showing signs of disease; while quarantine has come mainly to mean the detention of apparently healthy persons, usually at a frontier, lest they should be harbouring the germs of disease.

‡ *A Letter to the Right Hon. F. Robinson, M.P., President of the Board of Trade and Treasurer to the Navy, on The Plague and Contagion, with reference to the Quarantine Laws*, etc., by Augustus Bozzi Granville, M.D., F.R.S., F.L.S., M.R.I. London, 1819, pp. 29-40

In another letter, addressed by the same author in 1825 to the Right Hon. W. Huskisson, M.P., then President of the Board of Trade, the assertion is repeated, in a slightly different form. It is there stated positively that the forty days' quarantine was decreed in "an Edict of Justinian."

In neither letter is any indication given of the exact date, number, or title of the supposed edict. But in the earlier letter the following reference is given as the authority for the assertion: "*Follerius, in libello pro Custodiâ Pestis.*" A fairly diligent search, however, in the British Museum and other large libraries, lay and medical, has failed to bring to light this opuscule of Follerius.

The story of the great plague epidemic of Justinian's time is, of course, fairly well known. It began in Egypt in A.D. 542, spread to Syria, Byzantium, and Europe, and did not come to an end until the close of the century. It is possible—probable, indeed—that precautions of some kind, however rudimentary, were taken to check the spread of the pestilence from one country to another, or from one district to another. But, if so, no positive evidence, apart from Granville's assertion, is now available as to the nature of those precautions. It has further to be added that very considerable doubt must attach to his statement that forty days' detention was decreed in "an Edict of Justinian"; for, in the opinion of two authoritative writers on historical questions, no such law, decree, or edict was ever promulgated by Justinian. The late Dr. J. S. Reid, professor of ancient history at Cambridge, was good enough, a few years ago, to make some further researches for me in this matter, and he wrote: "I came to the conclusion that no such edict as that which Justinian was supposed to have issued in 542 against the plague ever existed." And again, the late Professor J. B. Bury, whom Dr. Reid further consulted, wrote: "No such edict as that supposed to have been issued by Justinian is extant, nor is there any reference to anything of the kind to be found in the historical authorities known to me."

Finally, Gibbon himself remarks on the lack of measures for checking the progress of the epidemic, in the following passage:

> "Those salutary precautions to which Europe is indebted for her security were unknown to the government of Justinian. No restraints were imposed on the free and frequent intercourse of the Roman provinces: from Persia to France the nations were mingled and infected by wars and emigrations; and the pestilential odour which lurks for years in a bale of cotton was imported, by the abuse of trade, into the most distant regions."*

It would seem, therefore, that the assertion that "quarantine," or a true forty days' detention of persons coming from an infected country, was an invention of the time of Justinian, must, at best, be regarded as "not proven," and must remain so unless and until the missing pamphlet of Follerius should be found and should contain some definite reference to the supposed edict enjoining that measure.

At whatever era in history the period of forty days was chosen, it is an unquestionable fact that, throughout the later Middle Ages and down to comparatively recent times, that period was most generally adopted for the detention of suspected persons. The reason for such choice has never been satisfactorily explained—unless it be, as some think, connected with the Hippocratic dictum that the fortieth day of a disease is a specially critical one.

Apart from the alleged edict (or edicts, for Granville, it will be noted, in his first letter, speaks in the plural—"the acts and edicts of some of the Oriental Emperors") of the sixth century, the earliest known record of a forty days' quarantine would seem to be contained in the first code of Venetian laws against plague, which are stated to have been drawn up probably as early as A.D. 1127. This, it is said, required all merchants and other travellers coming from the Levant to stay for forty days in the house of St. Lazarus before being allowed to enter the city.† Other instances of such true "quarantines" abound in later centuries, and it would serve but little purpose to cite specific examples. What is of more interest (and perhaps less well known) is that, so great is the power of tradition, the forty days' period of detention continued to be applied in some countries until comparatively recent times, and a few instances in support of this assertion may be given.

In Melbourne, Victoria, actually infected ships were subjected, in the earlier part of last century, to quarantine varying from seven to forty days. In the Virgin Islands forty days was the period of detention for a cholera-infected ship in the middle of the century. In like manner, in British Guiana, in 1851, when cholera was present in Jamaica, forty days' quarantine was imposed on arrivals from that island; and in 1854, when Barbados was infected, a quarantine of the same duration was, at the request of the principal inhabitants of the Guiana capital, applied to persons coming from Barbados. Again, in the Dutch possession of Curaçao, where the quarantinable diseases included "yellow fever, measles, small-pox, cholera, and all contagious diseases," actually infected ships were, in 1859, required to perform forty days' quarantine; while in another Dutch possession, Surinam, or Dutch Guiana, the same detention was imposed on cholera-infected arrivals. Later still, when, in 1874, plague (limited to five cases in the village of Namaz) had appeared in the Arabian province of Assyr, Egypt imposed a twenty-one days' quarantine on arrivals from the Hejaz, reserving the right to raise it to forty days "if positive news from a good source and from competent persons did not give assurances of an improvement in the sanitary state of Assyr and particularly of the village of Namaz."* Then, under the Austrian law of 1879, if a case of plague had occurred on a ship during its voyage, forty days' quarantine was applied in ports of that country without distinction of vessel.†

It is, however, unnecessary to quote further examples. It is beyond question that the conception of a forty days' detention—a true "quarantine"—dominated the whole world of sanitarians and administrators from quite early times down to comparatively recent decades; and this note has been written with the object of endeavouring to ascertain when that particular period came to be adopted, and in the hope that some reader may perhaps be able to throw further light upon the supposed edict, or edicts, of a Byzantine emperor or upon the lost pamphlet of Follerius.

F. G. CLEMOW, M.D.

* *Decline and Fall*, vol. v, chap. xliii.

† *The Nautical Magazine*, 1836, p. 982. Article by the late Sir Sherston Baker on "Quarantine in the United Kingdom and the Public Health Act of 1836." The authority for the statement is not given.

* *Procès Verbaux* of the Constantinople Board of Health, November 17th, 1874.

† "*The Laws relating to Quarantine . . .*" by Sir Sherston Baker, London, 1879 (from which some of the other statements in the text are also quoted). In the year 1879 most nations took unusually severe precautions, owing to the outbreak of plague at Vetlianka and other places on the Volga.

ASTHMA RESEARCH COUNCIL.

MEETING AT THE MANSION HOUSE.

THE objects of the newly formed Asthma Research Council were expounded, and an appeal made for financial support, at a large public meeting held at the Mansion House under the presidency of the Lord Mayor of London (Sir KYNASTON STUDD) on the afternoon of January 15th. A letter was read from Mr. Neville Chamberlain expressing the interest of the Ministry of Health in what was proposed.

Sir HUMPHRY ROLLESTON gave an address on asthma as one of a large group of idiosyncrasies. Persons who suffered from asthma and allied conditions, he said, had unluckily a special constitution, with a peculiar responsiveness to things which did not trouble ordinary people: thus a process essentially the same might result in diseases which, being in different parts of the body, appeared to be quite unlike. If the bronchial tubes of these hypersensitives were affected they had asthma; if the skin bore the brunt they got eczema; if the stomach and intestines reacted they had acute indigestion, vomiting, or "colitis." This hypersensitiveness probably played a part in other disorders, such as migraine or sick headache ("the disease of great minds"), gout (which was said to attack more wise men than fools), and even a form of epilepsy. The frequency of these diseases of allergic origin, Sir Humphry Rolleston continued, was unknown, but they were probably much commoner than might be thought. Research into the

causation and treatment of these many conditions would therefore benefit far more people than those who had frank asthma, and very probably would throw light on other diseases. Hypersensitiveness to foods, pollens, emanations, and so forth could be removed by desensitization, though more information was needed to perfect this method. Scientific research, said Sir Humphry Rolleston in conclusion, was so specialized that its methods and language seemed difficult and perhaps unintelligible to the outside world, but it provided the new knowledge from which reliable and simple tests for the detection of the causes of disease could be made, and so cleared the way for the prevention of disease—the ideal of medicine—or for its cure.

Dr. ARTHUR F. HURST, who is chairman of the Medical Advisory Committee in connexion with the Council, said that he himself had been interested in asthma from a personal point of view for thirty-five years. The one thing he felt sure about with regard to asthma was that there was still no cure for it. He gave the audience some account of his own experiences with various treatments, including an intranasal treatment which was said to have led to the disappearance of asthma from Chicago. He had also been invited to a clinic in America where a cure by dieting was promised, but a friend who had undergone the treatment said that he preferred asthma to the diet. No wonder that the prospect of a new and well-organized attack on asthma from the point of view of causation was widely welcomed. So far it had been possible to organize three centres for research into asthma. The first was owing to the generosity of Mr. Campbell-Johnston, and was directed to methods of physical therapy. The first Research Fellow was sent to Mont Dore and Reichenhall, the French and German meccas of asthmatics, and afterwards to Vienna, Berlin, Bad Ems, and Hamburg. Recently Mr. Halley Stewart had provided a fund for the organization of asthma research clinics at Guy's and Great Ormond Street; at the latter it would be possible to attack the problem by investigating asthma in its simplest form in childhood. It was hoped before long to start asthma units at other general hospitals in London and the provinces. Dr. Hurst mentioned a number of large provincial hospitals which had agreed to provide research centres, subject to the necessary financial support from the Council, as recorded in the *British Medical Journal* of January 5th (p. 29). At Leeds General Infirmary and the Birmingham General Hospital it was hoped to start research work in the near future. At Bristol the Royal Infirmary and the University would co-operate. Only that day an offer of assistance in research had been received from the Faculty of Medicine of Sheffield University. The Council hoped to be in a position to finance further research at St. Mary's Hospital under Dr. John Freeman. At King's College the physiology of asthmatic spasm was being studied. Dr. Hurst pleaded for the endowment of whole-time or part-time fellowships which would attract men already interested in the subject and already trained as expert observers, who only required the opportunity to carry out valuable investigations. Another project was to send out one or more research fellows to study what was being done in asthma clinics in Canada, the United States, and Holland. Asthma itself, Dr. Hurst continued, hardly ever killed. Sir John Floyer, the author of the first book on the subject, "panted on to ninety," according to Dr. Johnson. But it caused much suffering and interfered with earning capacity. In some cases there was spontaneous cure, but the great majority of asthmatics had to fall back upon some palliative treatment. The injection of adrenaline made life bearable to many who would otherwise feel like the old farmer dying of asthma who told Dean Swift, "If I can get this breath once out, I'll take care it shall never get in again." But adrenaline and the various powders, cigarettes, and sprays were mere palliatives. The Council proposed to get to work on the investigation of the asthmatic constitution, and from that point of view there was a real prospect of curing asthma and not merely relieving it.

Dr. HURST moved a resolution commendatory of the work of the Council, and this was seconded by Dr. F. E. FREMANTLE, M.P., who, in passing, told a good story of an asthmatic lady who had sought the advice of some obvious quack, and, on being reproved by her physician, said she was sure he was a good man because he advertised in a religious paper. Mr. BEN TILLETT, who also supported the resolution, spoke as one who had been often incapacitated by asthma over many years, and mentioned that on one occasion he had a severe attack while staying in a hotel in Swansea. Near the hotel was a herbalist's shop, with the words "Sure Asthma Cure" in large type in the window. He went in and found the proprietor suffering in worse extremity than his own. Mr. Tillett paid a very fine tribute to the humanity and disinterestedness of the medical profession.

Others who spoke briefly on the subject were Lord KNUTSFORD, Lord GREENWAY, and Mr. P. J. HANNON, M.P., and before the meeting separated uniformed nurses collected from the audience a large number of cards bearing promises of donations.

THE HEALTH OF THE SCHOOL CHILD.

(*Concluded from page 78.*)

IN our last issue we gave a summary of the first part of the Report of the Chief Medical Officer of the Board of Education, which dealt generally with the elementary school child. The later sections of the report are concerned with exceptional children, with the children of the secondary schools, and with several special subjects of inquiry.

Difficult Children.

Increasing interest is being taken, both by school medical officers and by educationists generally, in the physical and educational problems of the mentally retarded child. Allied to these problems are those of the nervous, unstable, maladjusted, and difficult child. The subject is one that has received special attention in Canada and the United States, and as an outcome there has been, since the war, a development of what are known as "child guidance clinics." The interest arose largely through the study of problems presented by the delinquent child. This work revealed how long and complicated was the history behind the delinquent act, and thus attention was drawn to abnormal traits in behaviour. There are in this country no clinics so fully developed as those in the United States, but a beginning has been made in some London hospitals, at Tavistock Square, the Jews' Free School, and the medical department of the London County Council. A great impetus is likely to be given to the movement by the establishment next year, under the auspices of the Child Guidance Council, of the proposed child guidance clinic in London, made possible through the generosity of the Commonwealth Fund of New York. The clinic has secured the full co-operation of the London County Council, which will be represented on the board of management, and will therefore be closely associated with education and the school medical service.

Defects of Vision and Speech.

London reports a gratifying decrease in the number of children certified as blind. The number of new cases between 1918 and 1925 inclusive was on the average 77 per annum (ranging from 59 to 89). In 1926 the number was 33, and in 1927 35. An analysis of the figures shows that a considerable part of the decrease is in those cases in which blindness is associated with venereal disease, and may be due to the great improvement in supervision and treatment brought about by the scheme for the diagnosis and treatment of venereal diseases, and by the closer supervision of midwives. Investigation of the physical conditions of children with high myopia shows that the percentage of under-nourished children is two and a half times as great as among the ordinary school population, and that after allowing for the children operated upon for tonsils and adenoids the percentage requiring operation is twice as great as that found amongst ordinary children.

Dr. Betenson of Cardiff investigated the condition of 452 stammerers, of whom no fewer than 371 were boys, and

only 81 girls. He reports that there appeared to be no connexion between stammering and any of the forms of left-handedness.

School Desks.

School desks are a perennial source of interest. One after another new types of desks have been evolved, only to prove in practice not to fulfil the hopes of perfect results which have been held out. It is not good physiology for children to remain at a desk for the greater part of a morning or afternoon, and the most perfect adaptation that could be possible of desk and seat to anatomical measurements of a particular child could not ensure throughout a session that the children would maintain correct postures. There has been a revolt against foot-rests. More significant than the question of modification of school desks is the revolt against desks altogether, which is gradually gathering head, and has taken especially the form of the substitution of tables and chairs, an experiment which is being watched by the medical staff with much interest and sympathy. This reform is generally to be welcomed as it is a move towards greater freedom. The combined desk and fixed seat is rigid. Separate and movable chairs give an increase of freedom of movement which is a boon. Already desks have been banished from the infants' departments.

The Secondary School Child.

The general inference drawn from the figures and reports of the school medical officers is that the incidence of definite malnutrition is less in secondary school children than in the elementary school children. On the other hand, the incidence of subnormal nutrition is greater. Further, it appears that the state of subnormal nutrition is more common in secondary school girls than in the boys. The greater stress and competitive strain of secondary school life, acting at a time when strain has its dangers, may be one factor producing this result. Outside school environment may contain other factors of equal importance. The domestic responsibilities often undertaken by girls, limiting their opportunities for physical recreation in the open air, combined with the anxiety of examination work, may account for the incidence of subnormality falling more heavily upon them. The incidence of defects of nose and throat ranges between 25 and 29 per 1,000, which compares favourably with the figure for elementary school children, which is 67.4 per 1,000. The large majority of such patients are suffering from enlarged tonsils and adenoids. An examination of the records of reformatory school children between 12 and 17 years showed a much higher percentage of abnormal throat conditions. Among 487 boys of ages 16 to 17, 30 per cent. were found with slightly enlarged tonsils on admission, while another 9 per cent. had marked enlargement.

Writing on the occurrence of defective vision in secondary school children, Dr. Auden of Birmingham draws attention to the fact that errors of vision may remain latent in the earlier years and become apparent as the demands upon the eyesight increase in later years. He thus raises the all-important question of what is the effect of the secondary school curriculum on eyesight. If the greater demands on eyesight tend to produce defective vision, then we should expect a significant increase in its incidence as we ascend the age groups of secondary school children. Evidence on the whole confirms this expectation. Defective eyesight is more frequent in girls than boys. The general incidence of defective vision increases with age in secondary schools; further, the occurrence of more marked errors of refraction is greater the higher the age group. There is, therefore, definite deterioration of vision.

The survey of the incidence of various defects found at the medical inspection of secondary school children leads to the general conclusion that their health as a whole compares favourably with that of the elementary school children. With the exception of minor conditions of subnormality, rightly or wrongly attributed to overstrain, all other specific medical defects are less common in the secondary scholar. But there is evidence that the elementary school child is improving at a greater rate than the secondary school child. The latter, as a rule, attends a better equipped school and has a midday meal at school; there is a general tendency for his defects and their treatment to receive more attention. Yet there are disadvantages. There is usually a longer school journey; there are longer hours of study, more home-lessons, and more pressure and keenness to excel.

The Young Worker.

One of the aims of the school medical service is to turn out strong men, healthy citizens, and efficient workmen. It is claimed that this aim is to some extent secured; there is a measurable improvement in the state of the leaving children; but when they leave school they tend to go backwards in health. There is no continuity in health action apart from certain movements such as boy scouts and girl guides. There is a gap between the age of 14, when the child leaves school, and 16, when the benefits of the insurance medical service begin. Ample evidence is forthcoming that by the close co-operation of education with industry much and lasting benefit may accrue to the young employee and correspondingly to the industry in which he is engaged. There is the certifying factory surgeon, but his duties are well defined and limited. He must examine all candidates for work within a certain stipulated period of their employment inside a factory. His examination is to determine fitness or unfitness, and no more. There is evidence that the certifying factory surgeons are in favour of an arrangement by which medical histories of the child during pre-school and school age would be at their disposal, especially in cases of disease of respiratory organs, myopia, rheumatism, and heart disease. But this provision would not bridge the gap of the two years. Many large firms, by the institution of factory welfare schemes, have done much to meet the difficulty, and despite industrial depression these schemes are steadily expanding in scope and number. The chief inspector of factories reported in 1925 that this form of welfare is definitely established in industry and is operating on a far larger scale than is generally realized. The movement was initiated by philanthropists, but it was soon found that the gain in health, happiness, and working capacity of the employee more than repaid the expenses incurred in conducting the welfare schemes. Sickness decreased and output increased. A comprehensive scheme provides for the medical inspection and treatment, dental treatment, physical training and games, canteens, social training and recreation, and education of employees. Many examples are given of the arrangements made for this useful work. In a sense it is the answer to the question, "What does the business man think of the school medical service?" The business man knows that prosperity depends upon efficiency. He finds that a more efficient youth is turned over to him from the schools, and he finds that similar and continued care of his employee maintains and increases his efficiency. It is held, therefore, that more systematic action to fill the gap between 14 and 16 is needed.

Health Education.

It is urged that every elementary school in the country chargeable to the rates and taxes should give practical and sensible health teaching, and that such teaching should never be neglected or allowed to fall into abeyance. The study and practice of health must from the first form part of the everyday life of the school. Hygiene should be systematically taught at least once a week, and practised every day, throughout the nine years of the child's school life. The instruction should be given, as a rule, by the school teacher, from the one with whom the child is most often and most closely in contact. The Board of Education issued last year a new *Handbook of Suggestions on Health Education*. One part contains hints for the training of children under 11 years of age, another for the elder children. The Board has announced that a knowledge of the contents of this handbook should be regarded as part of the necessary equipment of every teacher. All classes of the community desire knowledge and guidance in regard to a healthy way of life. There has probably never been such eagerness to know about these things. Some of the great newspapers have sought to meet the need by giving health instruction in plain and homely words. Sense of proportion may at times have been lacking, but the better

sort of articles have probably done much more good than harm. For future enlightenment it is necessary that every school in the land should make the science of health an integral part of its everyday life.

Feeding of School Children.

There is much else in this report that merits close attention, particularly the beginnings of the teaching of "mothercraft" in the girls' schools; the general improvement in the development of physical education and games; and the provision of school meals. In the last section it is noted that in 1921 and 1926, the years of coal stoppage, school meals went up from an average of ten million meals a year to sixty and seventy million meals. There is, therefore, evidence that the purpose of the school meal provision is being diverted from its original purpose to become a sort of poor relief, to feed the hungry. Special investigations were made into the state of the children in South Wales and Durham, and it was found that the children were no worse than the average attending the elementary schools in their district. The investigators were surprised that there were no greater manifestations of excessive sickness and impairment of health; but whilst no literal starvation may be evident many silent people are not having as much food as is necessary for their health and mere physical efficiency, and still more are passing through a period of grave mental distress.

The Need for Research.

The section upon the investigations and research work done by the school medical officers is worthy of study. It is urged that if a good return is to be obtained for the money spent on medical inspection school authorities should encourage work of this kind, and take it into account when considering the size and nature of their medical staffs. School medical officers have exceptional opportunities for research which are denied to most of their profession, in that they have a complete section of the population available for their field of investigation.

England and Wales.

Care of the Mental Defective.

THE activities of a large number of voluntary organizations, public bodies, institutions, and homes concerned with the welfare of mental defectives and other persons coming under the supervision of the Board of Control are co-ordinated by the Central Association for Mental Welfare, whose annual report for the period 1927–28 has just been issued. The Central Association acts as a means of communication between the local voluntary organizations and Government departments and public authorities, organizes the training of teachers, visitors, attendants, and others responsible for the care and treatment of defectives, promotes, watches, supports, or opposes legislation relating to mental deficiency, and in general does whatever it can to induce to the efficiency of voluntary work in connexion with the mentally defective. The Mental Deficiency Act, passed in December, 1927, and now in force, was drafted by the Board of Control in consultation with the president and other members of the Central Association for Mental Welfare, the association as a whole carrying out an active campaign to secure its passage. Propaganda and education—the former by means of lectures, films, and publications, the latter by means of special courses of instruction in psychiatry and allied subjects—are among the association's chief activities. During the year under review it organized separate training courses for social workers, medical officers, teachers, and magistrates. Each of these courses fulfils a vital need. The training of social workers is essential for the maintenance of an adequate supply of competent and experienced people to fill vacancies as they arise in administrative, teaching, or nursing work for defectives; the courses for medical officers provide those attending with the opportunity, usually otherwise lacking, of visiting a number of institutions, schools, and homes, and making a comparative study of methods of supervision and treatment. Magistrates require a knowledge of legal administration under the Mental Deficiency Act, and, so that injustice may be avoided, an understanding of the psychology of the juvenile offender; and, finally, the dearth of teachers for special schools and for special classes of dull and backward children can be met only by training suitable persons at courses conducted on the lines of those of the Central Association.

The Teaching of Cleanliness.

The Health and Cleanliness Council, which carries the excellent motto, "Where there's dirt there's danger," aims at spreading information by means of education and propaganda as to the advantages of cleanliness and other healthy practices, and at promoting cleanliness by co-operating as far as possible with other organizations engaged in similar work. Representatives of public health authorities, education authorities, boards of guardians, national health insurance committees, and various voluntary organizations, are associated with the council in its activities. The chief of these are the supply of posters, leaflets, and other publications to schools, clinics, and local authorities; sending lecturers and demonstrators to infant welfare centres, day nurseries, and schools at the request of the authorities concerned; and assisting organizations and local authorities during health weeks and baby weeks in connexion with local campaigns. In the council's fifth Occasional Bulletin, just issued, a survey is made of work done during 1928. This is a year the council can look back upon with some pride, for the records afford evidence of its extending activities and influence in connexion with all branches of its propaganda. A year ago the council announced that since its inauguration in 1926 it had distributed publications to 1,200 different areas; in the year under review it was in touch with approximately 2,300 districts in Great Britain. During 1927 the council sent out some 2 million publications; in 1928 this number had risen to 4½ million. The council has furthermore assisted in no fewer than 286 local health weeks, of which 156 took place during 1928. A travelling cinema under its control made its appearance during October, touring the country and displaying educational films, sometimes in streets, sometimes in halls. The council invites applications for the services of this cinema outfit, which has already been an asset to a number of localities conducting their own health campaigns. An indication of the response of school children to cleanliness propaganda is illustrated in some of their essays, written after receiving instruction from one of the council's lecturers, or by means of its literature or films, and reprinted in the Bulletin.

Health Visitors at Papworth Village Settlement.

A party of health visitors, drawn from the staffs of a number of local authorities, on January 7th visited the Papworth village settlement, where they were received by Dr. P. C. Varrier-Jones, who explained the methods employed in the cure of tuberculosis, in preventing its recurrence by providing patients with suitable homes, and in securing their re-establishment in appropriate occupations. He said that money spent on the institutional treatment of tuberculosis would be wasted unless adequate provision was made for the after-care of the patients. It was of the utmost importance that the breadwinner should be restored as soon as possible to a position in which he could maintain his family. In the course of the tour of the colony it was shown that Papworth is not only a sanatorium for the treatment of consumption, but a sociological experiment having for its purpose the effectual reduction of the incidence of the disease. The provision of the settlement is intended to counteract the common conditions under which treatment is often nullified by the return of patients to unhealthy homes, where many of them become, in spite of earlier efforts on their behalf, a burden upon their relatives and a source of infection. At Papworth, after patients have passed the convalescent stage, they become settlers in the village, single men and women being accommodated in chalets and hostels, while separate dwellings are provided for married men, where they may live with their families. In the workshops employment of

various kinds is provided, so that men and women can find callings which do not overtax their strength, but afford them an opportunity of regaining some measure of economic independence. The health visitors saw these establishments, of which an account was given in the *Journal* of June 30th, 1928 (p. 1115), on the occasion of the opening by H.R.H. the Prince of Wales of the cottages erected as a memorial to Sir Clifford Allbutt. When the grants paid by local authorities for the support of patients during their sanatorium treatment cease on the disease being arrested, the inmates of the settlement become wage-earners; they are remunerated by the management, who undertake the marketing of the goods manufactured. It is interesting to note that of the families who have entered the settlement to reside with former patients not a single member has contracted tuberculosis.

Central Midwives Board.

At a meeting of the Central Midwives Board for England and Wales on January 3rd, with Mr. L. H. West in the chair, in the absence, through indisposition, of Sir Francis Champneys, it was resolved—in view of the facts disclosed at the hearing of charges against two midwives at the last meeting of the Penal Board—that approval of training at the Wolverhampton District Nurses' Home, which expires on March 31st, should not be renewed after that date. It was decided that no new pupils should meanwhile be taken at the home, and that no application for re-approval should be considered before March 31st, 1930. Pupils now in training there who will not have completed their course by the end of next March will be transferred to other institutions or teachers. The Board appointed Dr. J. J. Jervis as its representative at the congress of the Royal Sanitary Institute, to be held at Sheffield in July, and Dr. R. A. Lyster as its representative at the congress of the Royal Institute of Public Health, to be held at Zürich in May. It was agreed that the Nether Edge Hospital, Sheffield, be permitted to train four pupils at a time instead of two.

Scotland.

Royal College of Physicians, Edinburgh.

THE annual dinner of the Royal College of Physicians of Edinburgh was held on January 11th, with Dr. R. A. Fleming, president of the College, in the chair. The principal guest was the Rt. Hon. Lord Elphinstone, K.T. The toast of "The Imperial Forces" was submitted by the vice-president, Dr. Robert Thin, and acknowledged by General Sir William Peyton, K.C.B., General Officer Commanding-in-Chief in Scotland, and by Sir Matthew H. G. Fell, K.C.B., Director-General of the Army Medical Service, who stated that the Royal Army Medical Corps was not receiving a sufficient number of new applications for commissions. The toast of "The Guests" was proposed by Dr. Alexander Goodall, and replies were given by the Rev. Dr. J. Harry Miller, moderator of the United Free Church of Scotland, the Rt. Hon. Lord Alness, Lord Justice Clerk, and Principal Sir James Irvine of the University of St. Andrews. "The Prosperity of the Royal College of Physicians" was proposed by Lord Elphinstone and acknowledged by the president.

Edinburgh Royal Infirmary.

The annual meeting of the court of qualified contributors to the Royal Infirmary, Edinburgh, was held in the City Chambers on January 7th. Lord Provost Sir Alexander Stevenson, who presided, in moving the adoption of the report, of which a summary appeared in the *British Medical Journal* for January 12th (p. 80), said that all-round progress has been a marked feature of the year, and recalled that on August 6th next the institution will have completed 200 years of work. He referred particularly to the fact that voluntary contributions last year amounted to over £72,000, an increase of £3,400 on the preceding year's total, and also to the fact that there was an increase of £5,690 on the gross income. After expressing gratitude to the students of Edinburgh University, whose efforts had raised £1,955, he said that the need for extension, which had been decided upon by the managers, was indicated by the existence of an average waiting list of over 2,000 persons.

Glasgow Royal Infirmary.

In accordance with a custom which has lasted over sixty years, the first day of the new year was celebrated at Glasgow Royal Infirmary by an annual meeting of the managers with the nurses of the institution. Lord Provost Mason, who presided, referred to the gratitude felt by the managers and by the citizens of Glasgow for the able work done by the nursing staff. Mr. James Macfarlane, chairman of the board of managers, made some reference to recent developments in the hospital, saying that he was glad that the buildings, which for the past six years had been constantly undergoing additions, were for the present complete. The high standard of efficiency which had been reached by the medical and nursing staffs, he continued, might be gathered from the fact that the average duration of stay of patients in the hospital had been reduced to seventeen days as compared with thirty-two days in 1897. The financial position of the hospital was such that all the available free capital was now in stone and lime; the buildings had been equipped to the highest possible degree, and what was chiefly required now was annual income. A favourable feature in this respect was that the contributions from employees in the past year had amounted to £28,661, which was £962 in advance of the amount contributed in this way during 1927. They were faced, however, with a deficit of £11,282, although this was smaller than the deficit a year ago, which had amounted to £12,896. The prizes gained by the nurses in examinations were thereafter presented.

Presentation to Dr. John Harrison.

A public meeting, at which the Rev. Dr. Gillies presided, was held in the Parish Church Hall, Lesmahagow, on January 11th, to celebrate the completion of fifty years of medical work in the town by Dr. John Harrison. The chairman remarked that Dr. Harrison had taken up practice in Lesmahagow shortly after graduating M.B., C.M. at Glasgow University in 1878, and for fifty years had pursued his labours in the parish of which he was a native. His work had gained great appreciation from the residents, as was shown by the representative meeting which had met to make the presentation. Unfortunately Dr. Harrison had been indisposed for some time, and was unable to be present to receive the gifts in person. Arrangements had, however, been made for a special wireless installation, by which he was able, from his bedroom, to listen to the speeches made at the meeting.

New South Wales.

[FROM OUR CORRESPONDENT IN SYDNEY.]

The University of Sydney.

THE University of Sydney a year ago, on the occasion of its seventy-fifth anniversary, launched an appeal for funds, and set the sum of £250,000 as its goal. A year was devoted to the collection, and when the fund closed in September last over £350,000 had been received. Among other sums was one of £20,000 given by Dr. Gordon Craig for the foundation of a fellowship in urology. Mr. George H. Bosch gave property to the value of roughly £250,000. Mr. Bosch in 1927 presented to the university the sum of £27,000 for the endowment of a chair of histology and embryology, and for assistance to the research work in the department of anatomy. In 1928 city property to the value of £220,000 was added. The donor, in his deed of gift, expresses the belief that it is in the best interests of the medical faculty that there should be full-time professors of medicine and surgery, and that there should be a department of bacteriology in the university, the professors devoting their whole time to university duties. Accordingly he offered the university—to provide for these appointments and for new buildings and equipment—city property and securities to the value of £220,000. From the trust fund

so established the income is to be applied in paying the professors of surgery, medicine, and bacteriology such salaries as shall enable them to devote their whole time and attention to their duties at the university. Additional income is to further the teaching and research in branches of medical science, particularly in medicine, surgery, obstetrics, bacteriology, and paediatrics. The Bosch professors of medicine and surgery are to act also as directors of studies of clinical medicine and clinical surgery, and to undertake and direct clinical research. The donor provides that the extra payment to the professors of medicine and surgery shall be conditional upon their being appointed in the first instance for seven years, subject to renewal for such a further term or terms as the Senate, on the report of a select committee, shall agree. The deed also provides that, if full-time chairs of medicine and surgery are found to be not in the best interests of the university, the Senate may appoint part-time professors, and that the income so set free shall be devoted to medical research in several branches. Any income not expended on the above-mentioned objects may be expended on departments in the faculty of medicine as shall best further the interests of the faculty, with a proviso that the expenditure shall not be more than one-sixth of the revenue from the investment of the trust funds, it being the intention of the donor that the costs of subsidiary services usually paid by the university out of its general revenue shall continue to be so paid, and not be a burden on the fund.

New B.M.A. Building, Sydney.

A contract has been signed for the erection of new premises for the New South Wales Branch of the British Medical Association. This has been rendered necessary by the resumption of the present premises by the city council for special and important purposes. A description of the design selected was published in the *Supplement* of August 11th, 1928 (p. 92). The new building, which will contain twelve stories and a basement, will be built on a 60-ft. frontage, and, in addition to lecture hall, library, and committee rooms, will accommodate the staff of the New South Wales Branch of the British Medical Association. The cost of the land was £45,000, and the building will cost £130,000. It is to be hoped, in addition to housing the Association, that the portion of the building to be let to tenants will show a profit, and that the moneys derived from this will be expended on benevolent relief and scientific work.

The College of Surgeons of Australasia.

The first annual meeting of the College of Surgeons of Australasia was held at Canberra on March 31st, 1928, with Sir George Syme, the president, in the chair. There were on the platform His Excellency Lord Stonehaven (Governor-General of the Commonwealth of Australia), His Excellency Sir John Goodwin (Governor of Queensland), the Hon. Earle Page (Treasurer of the Commonwealth), Sir Neville Howse, V.C. (Minister for Home and Territories and for Health of the Commonwealth), the Hon. W. G. Gibson (Postmaster-General of the Commonwealth), and Senator A. J. McLachlan. Delegates from the universities of Australasia were presented, and Sir John Goodwin and Mr. Victor Bonney of London were elected honorary Fellows. The Commission of the Federal Capital Territory at Canberra granted to the College, for future buildings, a site of three acres in the area reserved for scientific societies, immediately opposite the site for the University and next to the site of the Museum of Comparative Anatomy. A discussion on the improvement of hospitals and hospital methods was held, and a series of resolutions was adopted urging the need for providing opportunities for affording hospital training for surgeons, dealing with the question of payment of hospital staffs and with their appointment, and defining the views of those present on the relations between public hospitals and their patients. Resolutions emphasizing the importance of providing for post-graduate instruction in surgery and for medical research in teaching hospitals were also adopted. The rest of the meeting was devoted to scientific papers and discussions. During the latter half of 1929 clinical meetings were held in various Australian States and in New Zealand.

Reference to the fact that the *Journal of the College of Surgeons of Australasia* made its first appearance in July last appeared in the *British Medical Journal* of November 17th, 1928 (p. 906), when a brief account was given of the early history and constitution of the College and of its present position.

Correspondence.

FRACTURE CLINICS.

SIR,—The paper on fractures of the lower end of the radius in adults, by Mr. Harold Edwards and Dr. Bellis Clayton, which appeared in your last issue (p. 61), seems to me to furnish an excellent illustration of the benefit to surgery and the public which such a fracture service affords. It seems that at King's College Hospital, at any rate, the treatment of fractures of the upper extremity is well organized, more or less upon the lines advocated by Sir Robert Jones at Bath in 1925, and by Professor Hey Groves in his address published by you on December 1st, 1928 (p. 993).

It is to be hoped that fractures of the lower extremity are as efficiently treated at King's College Hospital as those of the upper, but in the former case the difficulty of want of beds may come in the way. Since the meeting of the British Medical Association at Bath in 1925 you have more than once advocated the establishment of fracture departments in general hospitals, but so far as I know without much result. This is the more surprising because at the Bath meeting of the combined Sections of Surgery and Orthopaedics the opponents of change, as represented by Mr. Gask, admitted that it was desirable that a special hospital for the treatment of fractures and for clinical instruction should be established in London. This is more than Sir Robert Jones or Professor Hey Groves has asked for. Those of us who were present at that meeting were struck by the overwhelming evidence of a desire for a radical reform of methods of dealing with fractures in hospitals.

In a letter published in your issue of December 15th, 1928 (p. 1108), Messrs. Seymour Barling and Percival Mills of Birmingham criticize the scheme outlined by Professor Hey Groves. While they recognize the importance of the part to be played by the general practitioner in the treatment of fractures, and the need for his better instruction, before or after qualification, they dislike the idea of a fracture department under a special surgeon and his team, and advocate that it should be placed under four surgeons and four assistant surgeons. In Birmingham general surgeons may be more keen upon fractures than they are in London, but if they are not, it seems likely that the "senior resident or registrar" who is to "exercise general supervision, initiate the new house-surgeons into the work of the unit, and be responsible for out-patient fractures attending the clinic" would very soon become in fact the fracture specialist to the hospital, and the outcome of the one scheme would be very much the same as that of the other.

To an onlooker the crux of the whole fracture problem is made up of the lack of interest in fractures which is shown by many general surgeons, and the lack of beds in which fractures of the lower extremity can be adequately treated; if these deficiencies were remedied sound principles and methods could be inculcated. Messrs. Barling and Mills do not discuss this last difficulty, which Professor Hey Groves would solve by utilizing the municipal hospitals and adding to their staffs and equipment. This seems to many of us a promising way out of the difficulty of want of beds, but the suggestion is often met by the objection, made again by Messrs. Barling and Mills, that its adoption would involve ignorance of fracture treatment by students. But how much useful knowledge of the treatment of fractures of the lower extremity does the student acquire under the old system, and is not the ultimate benefit to the patient to be more considered?—I am, etc.,

MELMEAD LITTLE.

London, Jan. 13th.

TREATMENT OF VARICOSE ULCERATION.

SIR,—In your issue of January 12th (p. 83) Dr. Bourdillon asks for some further data in connexion with the report on this subject (December 22nd, 1928, p. 1144).

As regards the duration of ulceration prior to the treatment it might be possible by again going through the 1,092 returns to furnish the information in some (perhaps in most) of the cases, but many were relapses which finally healed. I will bring the matter before the committee concerned in the investigation, with a view to a decision whether this further work should be undertaken. The extent of the ulceration prior to treatment was given in diagrammatic form in most of the cases, but I found it impossible to tabulate this information.

With regard to Dr. Bourdillon's inquiry as to data concerning the use of two or more methods of treatment for one case, I at first endeavoured to collate such information, but abandoned the attempt on account of the fact that the material could not be tabulated, and would consequently in print have taken up several pages of the *Journal*, without, as I think, fulfilling any really useful purpose. In many of the cases several methods of treatment were tried, and those that were finally successful are the tabulated ones.

I am not quite clear whether Dr. Bourdillon has assumed that the 56.2 per cent. of all cases treated with rest in bed or its equivalent were healed. He states, "Since rest in bed alone will cure a large percentage of ulcers it is evident that the position of a method of treatment in Table XI may depend more on the extent to which the physicians insisted on rest (or on careful bandaging) than on the value of the special treatment employed." Here I can be of assistance to Dr. Bourdillon, since I find on reference to my notes that out of the 656 cases that were treated only eleven cases healed without the use of a direct application or treatment to the ulcers; ten were dealt with by rest in bed and bandaging or strapping, and one by strapping only without rest. With the exception of one of the cases which remained healed at the end of five years only short periods had elapsed since this healing of the ulcers and the returns of the reports of the other ten cases.

In conclusion, I would like to add that Dr. Bourdillon's criticism and suggestions are welcome and useful, since this somewhat novel method of collective investigation presents difficulties in collation; I cordially assent to his suggestion that in future investigations of a similar character the pertinent variables should be fully recognized.—I am, etc.,

Limpsfield, Jan. 14th. ARTHUR P. LUFF.

STATISTICS ON PUERPERAL MORBIDITY.

SIR,—Dr. Bethel Solomons, in your issue of December 22nd, 1928 (p. 1155), calls attention to the necessity for accuracy in taking a uniform standard of puerperal morbidity, and he refers to that which we have hitherto regarded as the B.M.A. standard. On January 5th (p. 40) Professor Francis Browne further points out that even if a standard were rigidly adhered to reliable data would not necessarily be obtained, and he illustrates his point. I entirely agree with both, for they are simply calling attention to the widespread feeling that the present statistics of puerperal morbidity are based upon data which are not only misleading but to a great extent valueless. Hitherto much confusion has existed when compiling statistics, both as regards the actual standard used and the method employed in obtaining it.

The letter by Dr. R. R. Armstrong in the *Journal* of January 12th (p. 80) should serve as a most useful fillip at a time when the true value of reliable statistics on puerperal morbidity has made itself so keenly felt. Dr. Armstrong took the trouble to approach Dr. Alfred Cox for an authoritative statement in regard to the generally accredited B.M.A. standard of 1905, and his reply is most interesting. Dr. Cox says: "It is unfortunate that this confusion should have arisen, but we shall have to abide by the decision of the Puerperal Morbidity and Mortality Committee in 1925."

It is impossible to emphasize too strongly the importance of what Dr. Solomons, Professor Browne, and Dr. Armstrong have pointed out—that is, the acceptance of a standard which will receive universal recognition in this country. We have at present two standards before us. (1) That which has been adopted by the Ministry of Health for the notification of puerperal pyrexia—that is, a pyrexia of 100.4° F. or more affecting a woman within twenty-one days after childbirth or miscarriage, and sustained for twenty-four hours on end or occurring more than once in any given twenty-four hours. (2) The other standard is that suggested by the B.M.A. Committee of 1925, which apparently differs from the former in this respect, that the words, "sustained for twenty-four hours" should read "*more* than twenty-four hours."

It is for lack of a definitely accepted standard that much valuable time has been lost and much valuable material has either been wasted or rendered incomparable. Perhaps some of your readers who are workers in this field may be able to put forward a suggestion whereby the leading maternity hospitals might be consulted in regard to the standard which each proposes to adopt for the future, as also the method of obtaining it. This would be an achievement of very considerable value.—I am, etc.,

University College, Dundee, Jan. 12th. JOHN MCGIBBON.

SIR,—I believe that a lengthy correspondence on this subject will not serve a useful purpose, but it should be of extreme value that such an important matter has been ventilated.

If a questionary were submitted to the various maternity hospitals of the kingdom I believe it would be found that the uniform standard of morbidity is the B.M.A. standard—that is, that if the temperature taken *in the mouth*, morning and evening, should reach 100° F. on any two occasions between the second and eighth days, the patient is regarded as morbid. All deaths, with or without fever, are included. We take this as our standard at the Rotunda in order that we may compare our results with others, but we are also "trying out" the Rotunda standard.

Evidently much confusion exists, and this is made very evident by the letter of Dr. Cox, quoted by Dr. Armstrong in your current issue. I suggest that the time has come to investigate this all-important subject once more, and that it might be well for those who are drawing up the programme for the next Annual Meeting of the B.M.A. to consider whether a discussion on puerperal morbidity might not be of interest and value to the profession and to the community at large.—I am, etc.,

Rotunda Hospital, Dublin, Jan. 12th. BETHEL SOLOMONS.

STREPTOCOCCAL VACCINES AND PUERPERAL SEPSIS.

SIR,—We welcome Dr. Colebrook's trenchant criticism (January 5th, p. 41) of our paper in your issue of December 15th, 1928 (p. 1082). We by no means surrender the view that streptococcal vaccine is of subsidiary importance in the prevention and treatment of puerperal sepsis as compared with conservative and aseptic midwifery, but we are glad to qualify the statement that puerperal morbidity, as defined by the Ministry of Health, is in the main due to *Streptococcus pyogenes*.

When our inquiry on the extern midwifery district of St. Bartholomew's Hospital was initiated in 1925 it was generally believed that *Streptococcus pyogenes* was responsible for the majority of morbid puerperia, and this was confirmed by Dr. Colebrook in a paper read before the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, December 3rd, 1925. Dr. Colebrook then stated: "As to whether the haemolytic streptococci play a predominant part in the localized puerperal infections one cannot speak with quite as much assurance, but our experience leads us to think that they do. Swabs taken with care from inside the cervical canal in non-septicaemic febrile cases usually give an almost pure culture of this organism." Substantiation by bacteriological tests was not possible in our own series of cases, for the women were delivered in their homes.

In view of the evidence Dr. Colebrook has now produced it seems that a whole variety of relatively innocuous

bacteria may cause pyrexia of moderate degree. Clearly, however, it is undesirable that the all-important question of the detection and prevention of major puerperal sepsis should be obscured by the consideration that cases of sub-ordinate clinical importance are often due to indifferent organisms.—We are, etc.,

RICHARD R. ARMSTRONG.
WILFRED SHAW.

St. Bartholomew's Hospital, London, E.C., Jan. 4th.

DENTAL CARIES AND VITAMIN D.

SIR,—The enormous importance of the fact that the family doctor and parents are for the first time presented with the possibility of preventing and of assisting in the treatment of dental caries prevails upon me to ask for further space in which to answer Dr. Sim Wallace's letter published in your issue of December 22nd, 1928.

I have renewed my acquaintance with Sir Frank Colyer's textbook, but I have failed to find any evidence which would show that an ounce or two of bacon or sugar have ever had any influence on caries. There are no records of feeding experiments with controls. There is plenty of indirect evidence that dental caries can be correlated with a diet rich in soft cereals and sugars, but the evidence is of a very general and diffuse nature. It will, of course, support equally well the lodgement theory or the deficiency theory. A school inquiry (quoted) as to the effect of eating sweets is worthless, as there must be innumerable uncontrolled factors in such work. Sir Frank Colyer's cautious conclusion—"A consideration of the question of etiology would seem to suggest that the prevalence of caries in modern races is due to the soft character of the food and the increase in the use of carbohydrates which undergo rapid fermentation"—is one to which I should imagine little exception can be taken by either side, as free use of such food implies in most cases a diminished intake of fat-soluble vitamins. In regard to bacon I still know of no evidence which shows that it is actually antagonistic to caries, and in fact a comparison of the dentures of my Jew and Gentile patients would, if it were not worthless, like so much of the quoted evidence, lead me to an opposite conclusion.

As a matter of fact the question of bacon and sugar does not affect the results of the feeding experiment (recorded on December 15th, 1928) in the very slightest, as on referring to the dietaries of the various groups recorded in Table III, as recorded in the paper itself and in the *British Dental Journal* of October 1st, 1926, it is clear that they all contained the same quantity of bacon and sugar. In spite of this the average number of new carious teeth appearing in one group was ten times that in the other group (2.4 against 0.2). Quite apart from comparisons the absolute figures are striking enough. Here were a group of children who had on the average over eight carious teeth per head and the teeth practically ceased to become carious.

To the thoughtful family doctor or parent the figures given in Table III of Mrs. Mellanby and Mr. Lee Pattison's paper will probably prove more stimulating than any theory, for here are some results of research which can be applied to practice without having to alter all the habits of the nation. We can all try it and see for ourselves. It is, of course, open for a theorist to claim that the difference between these two groups is due to the oatmeal which was in B_2 diet and absent from A_2, but the practical man will simply stop oatmeal and give cod-liver oil or some form of irradiated ergosterol and watch results.—I am, etc.,

A. E. BARNES.

Sheffield, Jan. 13th.

SIR,—I think the answer to Mr. Barwise's cheery suggestion (January 5th, p. 43) that the points at issue might be settled by a few crucial feeding experiments on animals is that Mrs. Mellanby has already reported quite frankly that she has been unable always to produce experimental caries in animals by feeding them with vitamin-D-deficient or saccharine diets. She has induced caries by the former diet, but for some reason the results vary. It is obvious that there is some other factor connected with resistance. Clinically, too, every unprejudiced dental surgeon I know has met with patients whose teeth remain free from caries in spite of the fermentable carbohydrate diet they consume, their neglect of the toothbrush, and the fact that the vitamin content of their diet is the same as that of other members of their family whose teeth are often carious. Susceptibility varies, moreover, in the same individual without appreciable variation of diet.

There are, however, two recent observations which are closely relevant to this problem. Dr. E. W. Fish has contributed a cogent argument to the effect that injured dentine, its circulation being destroyed, cannot react against caries; I have reported that in certain cases of cervical caries of the teeth, with acid food debris and materies alba adhering to the gum margins, body baths of ultra-violet light render the mouth self-cleansing and the cervical surfaces insensitive. It is true that such radiation induces the formation of vitamin D in the skin, and that vitamin D increases the calcium content of the saliva; but that is certainly not the only result of irradiation. Among the other results may be the factor or factors which we are seeking. Admittedly we are in a position to recommend a diet which promotes the formation of sound teeth and makes for their freedom from caries. We can avail ourselves of Mrs. Mellanby's work as well as that of Dr. Harry Campbell and Dr. Sim Wallace; and still there will be something more to learn about the causes and treatment of dental caries.—I am, etc.,

F. TALBOT.

London, W., Jan. 10th.

TREATMENT OF CANCER BY LEAD.

SIR,—In your issue of January 12th (p. 82) Mr. J. Basil Hume ends his letter with the following startling statement: "I am still of the opinion that the treatment of cancer by lead in its present form is wholly unjustifiable, if on humanitarian grounds alone."

I do not question that Mr. Hume was unable to help his patients with the preparation he used, but I do question his right to stigmatize the practice and discredit the work of others by so foolish a general statement. Others are able to help the unfortunate inoperable cases of cancer by the use of lead preparations. Why cannot Mr. Hume simply say that he was unable to do so? Instead he accuses me, and others, of unprofessional conduct, inasmuch as we continue to use a "wholly unjustifiable" remedy.

He states that his treatment converted some of his patients into physical wrecks; again I do not doubt him. But if he will come to the Bristol Royal Infirmary any Friday about 11 a.m. he will see about thirty patients with advanced and inoperable cancer, most of whom are doing very well on a lead treatment. He will find few, if any, "physical wrecks," except those just starting the treatment, and among the cases he will see:

Case W. Carcinoma of the breast, treated for fourteen months, the patient having received 0.7 gram lead metal. There has been much gain of weight and loss of symptoms; it is doubtful whether there is any cancer remaining.

Case M. Carcinoma of the prostate, treated for fifteen months. The fistula remains closed, and the patient has gained much weight, the only trouble being absence of control of the sphincter. He has received 1.2 grams of this "*unjustifiable remedy.*"

Case D. Epithelioma of the tongue. The patient has been treated for a year, and has received 0.8 gram metal lead; is quite well, and no evidence of growth can be found.

Case Cx. Recurrent epithelioma of the lip after two operations. The *patient has gained weight*, lost symptoms, and appears to have been freed from his masses of cancer; he has received 0.6 gram metal lead.

Case C. Large sarcoma of ileum. The patient, who was unable to walk owing to paralysis and anaesthesia of the leg, has been treated for about a year. She is now very well and can walk several miles without any support.

Case E. Carcinoma of the rectum. The patient has been treated for ten months, and is now able to work again; has received 0.9 gram metal lead.

Case S. Rapidly growing ovarian carcinoma, with recurrence in operation scar, and ascites. The patient has been treated for seven months, and received 0.5 gram metal lead, she is now able to do her work.

These are a few instances taken at random from the patients who have received the largest amounts of this metal. Mr. Hume will see more cases than these, and can learn of other patients who, though now dead, yet proved that with this metal we have a hopeful beginning of a new system of treatment.

He can find an account of this treatment in the brochure *Chemotherapeutic Researches on Cancer*, published by Messrs. Arrowsmith, price half a crown. As it has not been reviewed so far by the English medical journals of wide circulation, Mr. Hume perhaps has some excuse for his unscientific statement.—I am, etc.,

Department of Pathology, Bristol University, Jan. 13th. A. T. TODD.

THE "CARDIAC SIGN" OF CARCINOMA OF THE STOMACH.

SIR,—In his valuable paper on carcinoma of the stomach in the *Journal* of December 29th (p. 1163) Dr. William Gordon states that diminution or absence of the cardiac dullness is a very valuable confirmatory sign when carcinoma is suspected, and he mentions only two other conditions in which this sign occurs—namely, starvation and severe diarrhoea.

If this statement goes unchallenged it may lead to many errors of diagnosis, for this absence of the cardiac dullness is very frequently found in simple cardiac weakness such as that which occurs after influenza or diphtheria; and complete absence of the cardiac dullness may sometimes occur when the heart weakness is not enough to prevent the patient from walking about and living a life of normal activity.

With regard to the explanation of this physical sign, several factors may be concerned. One factor—though not the commonest—is, I believe, a lessening of the elastic tension of the heart walls due to poor muscular tone. This is, I believe, the explanation of the cases occasionally met with where a heart is so greatly dilated that the apex may be in the seventh interspace in (or even external to) the anterior axillary line, but nevertheless the whole of the cardiac area may be resonant and no area of cardiac dullness can be defined. If a solid organ overlies one containing air, it will only give a dull note when sufficiently elastic to absorb the vibrations due to the percussion stroke, and thus prevent them from causing vibration of the air in the subjacent "resonant" organ. This change of quality owing to lowered elastic tension of an organ is well illustrated by the disappearance of the dullness of the liver in cardiac weakness, even when only slight.

These questions are discussed in a paper of mine in the *British Medical Journal* for June 27th, 1925, on "The estimation of the cardiac output"; and also in my book *The Early Diagnosis of Heart Failure* (London, John Murray; pp. 184–206).—I am, etc.,

Birmingham, Jan. 9th. T. STACEY WILSON.

SERUM TREATMENT OF SCARLET FEVER.

SIR,—With reference to Dr. W. Brown's article in the *British Medical Journal* of January 5th (p. 13) on the subject of the Dick test in scarlet fever, I notice that he calls attention to the possibility of patients treated with anti-scarlatinal serum giving a positive Dick reaction, indicating that they have probably not developed their own antitoxic immunity. The defensive forces of the body have not had to fight as they would have done in the absence of serum.

Having treated over 800 patients without a single death directly due to scarlet fever during the past three years in Darlington I have become convinced of the marvellous value of anti-scarlatinal serum in the treatment of all early severe toxic scarlet fever patients. I have not, however, tested the Dick reaction in cases treated with serum, but my attention has been drawn to the increased tendency for late complications in convalescence, particularly in the form of minor articular rheumatism with occasional cardiac involvement, beginning about the third or fourth month after attack, in patients who left the hospital perfectly fit in their fourth or fifth week. One of my serum-treated patients developed a typical attack of scarlet fever five months after the first attack, but, as Dr. Brown states, it is too early yet to look for confirmation of this aspect of the effect of serum administration, since the occurrence of second attacks of definite scarlet fever was not so rare as to escape recognition before the introduction of serum therapy.—I am, etc.,

January 7th. G. A. DAWSON, Medical Officer of Health, Darlington.

CARDIOSPASM OR ACHALASIA OF THE CARDIA.

SIR,—It is evident that Dr. Hurst believes that those who sow the wind should reap the whirlwind; his tempestuous comments on my contribution to this intricate subject (December 15th, 1928, p. 1110) are tinctured by a dogmatism that tends to cloud rather than clarify the obscurity. At the outset he and Mr. Rake challenge my statement that "the existence of any hypertrophy of the muscular coat remains a subject of contention." That statement may appear ambiguous, but reference to the context would have saved both of them much superfluous criticism, referring, as it does, to the cardiac sphincter and not to hypertrophy of the oesophageal wall. Hypertrophy of the oesophageal wall has been found by all observers so constantly that it has become accepted as an invariable concomitant of the disease. In the matter of hypertrophy of the cardiac sphincter it should suffice that Moore has recorded two cases and Brown Kelly one, where definite hypertrophy of the sphincter was found, to justify the assertion that there remains difference of opinion as to fact.

Dr. Hurst three times refers contemptuously to the futility of founding deductions on my "one case." Yet in the *Proceedings of the Royal Society of Medicine* of January, 1915, we find (following his injunction to "consult the extensive literature") that Dr. Hurst reported "a case of achalasia of the cardia," and on the strength of that "one case" deduced his belief that the term "spasm" was incorrect and that "similarly many cases of so-called pylorospasm are due to pyloric achalasia, and ileo-caecal achalasia is the most frequent cause of ileal stasis"—sweeping conclusions to base on so slender a foundation.

Despite the implications of his declaration that "the word was first applied by me in 1914 to the cardiac sphincter," etc., the plain truth is that the term "achalasia" (*a*, not; *χαλάω*, I relax) was coined by Sir Cooper Perry and adopted by Dr. Hurst. Many years previously, in the *Transactions of the Pathological Society*, 1896, xlvii, 37, Sir Humphry Rolleston first suggested the pathology so strenuously advocated later by Dr. Hurst. It was Sir Humphry Rolleston's conception of a pathology that suggested to Sir Cooper Perry an alternative nomenclature. Since those days an enlarged experience and a more critical examination of the known facts have led many to believe that this pathology is inadequate, so that the term "achalasia" represents a premature attempt to crystallize in a word our conception of the disease. From 1913 onwards, until Walton's significant article in 1925, most of the published cases, treated by operation, were single cases.

Lest Dr. Hurst should feel any remorse for his temerity in publishing, with comments, his one case of achalasia, I offer this consolation, that more than fifty years ago (1877) James Paget reported one case of osteitis deformans so accurately and with such a wealth of acute observation that little of essential importance has since been added to our knowledge of that disease. Nor did Newton need to see more than one apple fall to enable him to make some very pertinent deductions as to the laws of gravity.

Treatment by bougies proving sometimes dangerous, often ineffective, and always tedious, a dilatable bag was devised by Plummer, who (with Vinson) reported in 1921 no fewer than 391 cases—some of these, however, required operation. The mercury tube is claimed to be more effective and to pass painlessly, but on these points there is divergence of opinion. In February, 1927, Mr. Harry Morley recorded in the *Lancet*, under the title "Cardiospasm," four cases. There emerge from his experience, from that of Walton, and from the experience of others, these facts—that the mercury tube does not always pass painlessly, that the passage is often difficult, that there is usually marked gripping of the tube, and that treatment by this means is tedious and often ineffective. Economic considerations (loss of time, loss of work, and the factor of expense) cannot be disregarded where alternative procedures are available. Mutch instances a case where the mercury tube required passing thirty-five times in one week, with little or no ultimate benefit; one of Morley's

patients, at the end of two years' treatment by the mercury tube, was "given a mercury tube to use daily." On the other hand, in Walton's fourteen cases, as in mine, operation conferred on the patient immediate, complete, and permanent cure, healing and complete convalescence being ensured within a fortnight.

Dr. Hurst might cease to refer to "Walton's operation" since the procedure of dilating digitally the cardiac orifice, after a preliminary gastrostomy, was first used and described by Mikulicz in 1881. Incidentally, Walton refers to it as "Mikulicz's operation."

Dr. Hurst seems to display a carelessness of statement and a disregard for logic when he says, "Hirschsprung's disease is probably acquired in early childhood, and is not congenital." Here he passes from the tentative "is probably" straightway to the definite "is not congenital." Again, "The relief following Walton's operation . . . the effect of which is to produce a more favourable postural tone of the sphincter" can scarcely be regarded as a pattern of lucidity; the term "postural tone" may hold some occult meaning for Dr. Hurst, but to less agile minds it requires further elucidation. In what way, precisely, is the tone of the cardiac sphincter modified by posture? Again, he tells us, "There is no question of *curing* this condition by any form of treatment . . . as the changes in Auerbach's plexus are of a permanent character, the hypertrophy and dilatation . . . remaining unaltered." It might induce Dr. Hurst to modify the confidence displayed in this *non sequitur* to learn that Plummer, out of the experience of 301 cases, declares that both hypertrophy and dilatation do disappear after the operation. The term "cure" has a definite meaning, being with reason applied to patients when all symptoms have completely disappeared, leaving no physical defect or depreciation in health. In this sense the cases treated by operation are assuredly cured, whatever term Dr. Hurst cares to apply to those treated by the mercury tube, who seem not infrequently to require daily, weekly, or monthly repetition of the treatment over an indefinite period.

There is no evidence of any change in the nervous mechanism of cases that recover. From such a mechanical obstruction death can only ensue as a direct result by starvation, or indirectly by a complication, as, for example, a mediastinitis. It must be a rare occurrence that, for lack of a gastrostomy, a case is allowed to terminate fatally from starvation alone, so that the changes in Auerbach's plexus found *post mortem* are not demonstrably due to the primary disease, but to the complication that caused death. Mere end-products seen in other terminal conditions are interesting, of course, but there are pitfalls in the way of correctly correlating them with the essential primary cause of the disease.

Professor Langmead is reported to have said at a meeting of the Brighton and Sussex Medico-Chirurgical Society that it was difficult to understand how a paralytic lesion could lead to hypertrophy down to the zone of structure, or how so much hypertrophy could result from obstruction imposed by a zone of muscle in normal tone.[1] Accepting the evidence adduced by Mr. Rake and others derived by dissection of advanced cases as to degeneration of the nerve fibres, it seems strange that an isolated area of degeneration can occur as a primary lesion in an otherwise healthy individual—it is assumed to be unnecessary even to hint at any first cause such as a toxaemia from syphilis or other known antecedent of a neuritis, etc. Again, as regards "spasm," Professor Langmead is said to have referred to the positive evidence of gripping by the cardia which was vouched for by some surgeons. Somewhere in the region of the diaphragm there must be a physiological sphincter, one capable of holding back for an indefinite period a column of food, 8 inches or more, against the powerful peristaltic contraction of an oesophagus with grossly hypertrophied walls. For this tonic contraction no better term than "spasm" has yet been found.

In cured cases, as frequently figured in the literature, and in my case, there remains for a time a flaccid dilated oesophagus down which the barium meal is seen on the screen to fall like a tenuous waterfall. As surely as hypertrophy of muscle only occurs in response to an intermittent obstruction, just as surely does atrophy occur when the obstruction has been removed and the muscle ceases to have work to do. The hypertrophy of the muscle of the oesophageal wall may be expected on first principles to disappear, and even if it can be proved that the dilated tube never regains its original calibre, so long as it fulfils its function of conducting food without let or hindrance to the stomach and no symptoms reappear, the mere existence of dilatation does not invalidate the claim to "cure."

In saying that cure does not occur because "the changes in Auerbach's plexus are of a permanent character," Dr. Hurst is again guilty of a *non sequitur*, since it is by no means proved that the changes found by Mr. Rake and others have anything to do with the true cause of the disease. To describe the essential cause as being due to an inco-ordination of the neuro-muscular control of deglutition only leads us to ask what causes the inco-ordination, and to that question there has hitherto been no adequate answer.

There is a paucity of information as to the habits of life, etc., in the recorded cases; perhaps a more searching inquiry into the previous history as to imperfect mastication and the bolting of masses of solid food, suggested by my case, may establish this as one at least of the primary causes. It is true that cases occurring at so early an age as 2 years are on record, but even at that tender age the bolting of food is not unknown. There remain those said to occur within a few days or weeks of birth; these are few in number and demand very careful analysis before being accepted as true cases of cardiospasm; Professor Langmead instanced two of these juvenile cases, one of which was completely cured by suggestion.

The operation is admittedly severe, but in careful hands it is reasonably safe (none of Mr. Walton's operated cases died); recovery and cure followed with impressive rapidity and with a completeness that inevitably challenges the tedious, protracted, and expensive course of those treated by the mercury tube; the scope of the latter method would appear to be in mild cases, or in cases complicated by some other serious disease. Certainly the results achieved by the mercury tube do not prove it to be the counsel of perfection in all cases, nor do they confer on their protagonist any prescriptive right to generalize and to refer disparagingly to the deductions of those who report single cases.—I am, etc.,

H. H. GREENWOOD.

Swindon, Jan. 9th.

[1] *British Medical Journal*, December 29th, 1928, p. 1180.

TONSIL AND ADENOID OPERATIONS.

SIR,—"Whenever a laryngologist brings forth some fresh instrument for the prevention of haemorrhage or to simplify the operation for the removal of tonsils and adenoids, I can tell exactly how far he has got in laryngology" is the saying of one of my former chiefs.

I can suggest no golden rule to meet every difficulty that may be encountered in the course of this perplexing operation; but having performed many thousands of operations by the guillotine method, and many hundreds by the method of dissection, perhaps I may be allowed to express an opinion on this somewhat worn subject. I have had only seven cases of haemorrhage in over 5,000 cases treated by the guillotine. Three of these required ligaturing; a gauze plug and Watson-Williams pressure forceps sufficed for the remainder. Haemorrhage after the guillotine operation usually means that a piece of tonsil has been left behind.

While admitting that dissection is the ideal surgical method, I suggest that it is one that cannot, as a general rule, be practicably applied in such large clinics as I have had to deal with. In dissection, haemorrhage will result unless care is exercised not to go beyond the capsule or to injure the faucial pillars. Anything that Mr. Tilley says must be taken as advice from a teacher; I am heartily in agreement with him.—I am, etc.,

J. ALDINGTON GIBB.

Maidstone, Jan. 7th.

SIR,—I can never understand why the tonsil should recurrently be the butt of controversy as regards the risks of haemorrhage, and why a blood vessel in this situation cannot be treated as elsewhere on plain surgical principles—namely, by picking it up, leaving a forceps attached, and proceeding with the dissection. As I said some time ago at the discussion on anaesthetics at the Laryngological Section of the Royal Society of Medicine chloroform is the best anaesthetic in tonsil surgery, but it demands the best administration. If well given the patient is got quickly under without struggling, and is kept sufficiently deeply under to avoid disturbance as the dissection goes on. The instrument employed is a first essential. After many years' experience I have ended in using only my own dissector (Mayer and Meltzer), which is blunt, slightly curved at one end, and more so at the other, with which instrument the turning-out of the tonsil can be quickly and safely proceeded with; by the invention of long, curved artery forceps (Allen and Hanburys) any bleeding vessel can be readily caught. I also thought out a specially large, oval-shaped, serrated-edged guillotine, which has been very useful for adults, judging by its sale. With this the tonsil can be rapidly and safely evulsed when preferred to dissection.

I have given much attention to this subject of tonsillar haemorrhage, and would certainly never ligature if at all avoidable, since the spot tied must become septic. I consider the use of pressure forceps far preferable for safety, celerity, and efficacy. I cordially agree, therefore, with Drs. Clarke, Lindley Sewell, and Horgan, and cannot speak too strongly against ligature.—I am, etc.,

London, W.1, Jan. 12th. WM. STUART-LOW.

SIR,—Three months' use of the La Force guillotine had led me to discard it for other methods. The disadvantages of this guillotine operation appear to be, first, its tediousness, even in adult cases, and its impracticability when faced with long lists of children; secondly, its doubtfulness (in my experience) as regards complete haemostasis.

One can tell pretty well beforehand if haemorrhage is going to be troublesome by taking notice of the condition of the anterior pillar, especially in its superior part. If adherent and its margin not properly defined, haemorrhage may be troublesome, especially if the tonsil is small and fibrotic. It should be the surgeon's first thought before the use of the blunt guillotine to have a free pillar by stripping it back with tissue forceps; or if its anterior edge is well defined, and the tonsil large and not fibrotic, to see that the guillotine blade does no damage. If, by the aid of an electric head mirror (the patient on the back with the head well down, pharyngeal reflexes abolished, and the air-way clear), large cotton-wool swabs attached to tapes are placed in the tonsil fossa after complete enucleation one need have very little bleeding. If the anterior pillar is well adherent and the tonsil small and fibrotic the only practicable procedure appears to be dissection. Very little is heard nowadays about the cold wire snare which appears to be a surer method of compression than that obtained by the La Force guillotine.—I am, etc.,

Manchester, Jan. 12th. L. D. MERCER.

SIR,—After tonsillectomy, by whatever method, it always appears to be waste of time to spend "a few minutes" trying to stop haemorrhage by the uncertain method of gauze pressure when the perfect security afforded by pressure forceps and ligature can be achieved in a few seconds.—I am, etc.,

London, W.1, Jan. 10th. H. MORTIMER WHARRY.

SACRO-ILIAC PAIN.

SIR,—In your issue of December 22nd, 1928 (p. 1157), there appears a report of a discussion at the Medical Society of London on sacro-iliac pain, and some of the statements seem to call for comment.

On the question of sacro-iliac displacement, Mr. P. Jenner Verrall gives the impression that "anyone who had felt or heard the click while performing the manipulations for reduction . . . must be convinced of its existence." This same click may be produced while manipulating the sound joint, and in fact may easily be produced in any of the spinal joints, so that it need not necessarily signify the reduction of any displacement whatever. It would, however, be easy to convince patients that something had been out of place, and one rather imagines that this explanation has been used by bonesetters and osteopaths to their advantage. The sound is in every way comparable to what takes place when people "crack" their fingers. There is no necessity to produce this sound when manipulating joints, but it is useful in letting the operator know that the joint has been moved to its *full extent*.

Mr. Verrall also thinks it impossible to perform manipulations of the sacro-iliac joint otherwise than under anaesthesia. Sometimes this may be an advantage, but I am daily manipulating sacro-iliac and lumbar joints without any anaesthetic, and usually they are not painful.

Dr. Wilfred Harris is reported to have said that "American surgeons particularly . . . had helped to rescue many sufferers with chronic pain in the back from chiropractors and osteopaths." With this we can all rejoice, though had we not hitherto neglected this subject the cases would not have drifted into the hands of those other practitioners.—I am, etc.,

London, W.1, Jan. 1st. THOMAS MARLIN.

ACTINOTHERAPY AND DEAFNESS: POST HOC OR PROPTER HOC?

SIR,—The following case, which occurred in this institution, may prove of interest to your readers.

A staff nurse, who has been with us for many years, had become progressively deaf. For all practical purposes she was stone deaf. Five weeks ago she was transferred to the charge of a large ultra-violet ray room, where all types of lamps, mercury vapour, tungsten, iron-cored, and carbon lamps, were used. She was on duty several hours a day and every day. Her hearing has undergone a remarkable betterment; indeed, to-day I carried on a conversation without having to raise my voice at all.

If progressive deafness is a degenerative process, as pointed out by Mr. Fred Stoker in his paper, "The nature of progressive deafness: a degenerative disease," the revivifying action of the rays might possibly be an explanation. As, however, I am not an otologist, and my aim is merely to record a case which is exceptional in that we do not find deaf nurses so constantly exposed to ultra-violet rays, I will only add the hope that I may not have given a further impetus to the charlatanism which besets this form of treatment.—I am, etc.,

Morpeth, Northumberland, Dec. 18th, 1928. T. C. HUNTER, M.D.

SO-CALLED "WHITE ASPHYXIA" OF THE NEWBORN.

SIR,—Like many others I have read with great interest Mr. Aleck Bourne's observations on the resuscitation of the "white baby." On one point, however, I venture to disagree, and that is his condemnation of the efficacy of mouth-to-mouth insufflation. In numerous cases I have seen excellent and almost miraculous results from mouth-to-mouth breathing, care being taken to prevent inflation of the stomach through the oesophagus by placing the hand on the abdomen and exerting a fair amount of pressure. May I make the instrument makers the present of an idea and suggest a rubber teat with a valvular opening to be placed in the child's mouth and a rubber flange to protect us from the unpleasantness of the little manœuvre?—I am, etc.,

Ashton-under-Lyne, Jan. 8th. MARGARET GORMAN.

ASTHMA.

SIR,—What was the urgency or necessity for the intensive publicity campaign in the daily and evening papers of January 11th, proclaiming that there is no cure for asthma? In the past these unfortunate people, the asthmatics, have been treated as neurotics, and their symptoms stigmatized as nervous manifestations, and they were told they were incurable. While admitting that we are painfully ignorant of the full biochemical phenomena taking place in this complaint, certain procedures have

been discovered in recent years which have led to such an amelioration of symptoms as many patients are satisfied to call a cure. Instead of reiterating the ancient parrot cry that there is no cure for asthma we can now encourage the asthmatic by telling him of the great advances made in treatment, and that, with few exceptions, there is hope for all.

The following methods of outstanding value have each cured scores of cases: The regime of diet and exercise advocated by Dr. John Adam, the intravenous injection of peptone of Dr. Auld, the mixed coliform or entero-antigens of Professor Danysz, the radiation of the chest of Mr. Gilbert Scott, the use of tuberculin and other work of Professor Storm van Leeuwen, and last, but not least, the dermal reactions as elaborated by Meltzer and other American workers. Given a knowledge of the various types of asthma there is only one that is at present incurable, though even that type may be helped.

Naturally I am entirely in favour of all research which may throw light on the problems of asthma, but I consider the public will be more ready to subscribe to a venture that has paid a dividend and can promise more than to one which advertises its insolvency, especially as I, for one, believe the latter assertion to be untrue.—I am, etc.,

London, W.1, Jan. 12th. FRANK COKE.

*** While the bald statement that there is "no cure for asthma" may give a wrong impression, it is far less misleading than to announce that "a certain cure" for asthma has been found. The position was accurately and concisely stated by Sir Humphry Rolleston, Lord Dawson, Dr. Hurst, and Dr. Fremantle in their letter printed last week at page 84: "there is not any one form of treatment which is effective in all cases of asthma."

TUBERCULOSIS BOARDS.

SIR,—Dr. T. Readman, in his letter under this heading (November 10th, 1928, p. 868), makes the cruel insinuation that 75 per cent. of the men who were discharged from the army suffering from tuberculosis have not got the disease and probably never had. It would be most interesting to know the official percentage of men who were originally discharged as suffering from this disease and who have since died from it. Many of those who are left have learnt to take care of themselves, and should go on for an indefinite period, provided they are not badgered and worried over their pensions.

Dr. T. Readman also states that he is of the opinion that if a man really has tuberculosis which originated in the war he will not now be in a condition to take a railway journey of, say, four hours each way. If this is really his opinion it merely demonstrates that, although he is a medical superintendent of a sanatorium, he has not yet grasped what can be accomplished by prolonged and intelligent sanatorium treatment, followed by a quiet, well-regulated life in the country. I have personally found sanatoriums and sanatorium treatment to vary greatly in quality. If Dr. Readman's patients have all been looked upon as potential malingerers, to perhaps the extent of 75 per cent., it is not surprising that after ten years they are either dead or bedridden.

I have the misfortune to belong to the group of disabled men whom he goes to such pains to malign. I have suffered from tuberculosis for the last twelve years. At times I am perfectly healthy and strong, at others I have positive sputum, night sweats, slight fever, etc. As a result my practice is small, but nevertheless it contains three men who contracted tuberculosis in the war, and who, in consequence of the very careful life they have led, are still able to enjoy prolonged periods of almost perfect health. If they were examined at such a time by a trio of medical men with a similar outlook to Dr. Readman they would undoubtedly have their pension reduced. The hardship thus entailed would no doubt seriously and irretrievably damage, if not destroy, their chance in the gallant fight they are putting up against one of the most disheartening and treacherous of diseases.—I am, etc.,

December 19th, 1928. M.B., CH.B.

LIPIODOL.

SIR,—May I express my agreement with Drs. F. G. Chandler and W. Burton Wood (January 12th, p. 84) in their dislike of the scalpel incision as a preliminary to lipiodol injection. Contrary to your reviewer I feel much safer with an instrument with a sharp (but short) point. When a moderately blunt point was used I found that much greater care was required in order to avoid injury to the posterior wall following the sudden cessation of resistance as the anterior wall is penetrated; this danger is increased by the fact that the trachea is so elastic that considerable flattening may take place before it is pierced. However sharp the instrument used, anyone with practice in pneumothorax treatment will have no difficulty in feeling the lack of resistance as the point enters the lumen of the trachea.—I am, etc.,

Mundesley, Jan. 14th. ANDREW MORLAND.

"THE RIGHT TO PRACTISE."

SIR,—Section 34 of the Medical Act, quoted by Dr. J. Gordon Macqueen, clearly defines what a "qualified medical practitioner . . ." means "*when used in any Act of Parliament.*" This in no way defines who shall or shall not practise. It is illogical to conclude that a person not "registered" is not a "duly qualified medical practitioner." A duly qualified medical practitioner is not bound to register. Such a person would have every "right" to practise, and would still legally be a "duly qualified practitioner."

I quite agree with Mr. W. E. Hempson that if every degree or diploma was taken away a man could still practise medicine or surgery, *but as an unqualified practitioner.* In fairness to me, he must see that my remarks applied to the discussion so far as a "qualified" medical practitioner was concerned.—I am, etc.,

St. Leonards, Jan. 5th. A. G. NEWELL, M.D.

Obituary.

FERNAND WIDAL, M.D.,

Professor in the Faculty of Medicine, University of Paris.

WE greatly regret to announce the death, on the night of January 14th, of Professor Fernand Widal. Our Paris correspondent, Dr. Gustave Monod, writes:

The standard-bearer of French medicine is dead. Cerebral haemorrhage has suddenly destroyed that beautifully organized brain. All round the world let us observe one minute's silence.

Widal was born in Algeria in 1862. An exceptionally brilliant student, he climbed up quite young the stiff steps of the various concours leading to professorship. Laboratory work appealed to him from the start, and the combination of both the gift for research and the gift of a born clinician seems to give the explanation of his exceptional contribution to modern medicine. Let us mention his method of cytodiagnosis, the agglutination reaction in typhoid fever which bears his name throughout the world, his studies on the influence of sodium chloride upon oedema. With Chantemesse he has been one of the promoters of typhoid vaccination. The hall-mark of his work is experimental accuracy, and his publications are clear and precise, giving every opportunity and facility for control.

Those who have visited his wards at the Hôpital Cochin know what an organizer he was. Every patient was examined systematically by the staff, and every morning the master sat at the bedside and started a sort of Socratic exposition, asking questions and inspiring answers. He began with the first-year man, and finally himself concluded in a few words. Once a week the theatre was packed to the ceiling when he delivered a clinical lecture, speaking for an hour in his easy way without referring to any notes. Those who knew him more intimately can be the witnesses of what careful preparation led to his apparent facility.

Widal was, and will remain, in our thoughts perpetually young. He said he had no time to grow white hair. His secret was work and the love of the young ones. Official

honours came in showers from his own country and from every scientific centre. But neither titles nor ribbons nor the praise of the world were his reward. May he rest in peace—he who has been to scientists the pioneer, to his patients the doctor, to his pupils "*le Patron*."

WILLIAM LATIMER STOREY, M.D.,

Honorary Secretary, Belfast Division, British Medical Association.

WE regret to have to record the death of Dr. W. L. Storey, one of the best-known medical practitioners in Northern Ireland, which occurred at Belfast on January 4th.

William Latimer Storey was a native of Quebec, but left Canada for Ireland at an early age, settling in Belfast, where he was educated. He received his medical training at Queen's College in that city, and graduated M.D., B.S. in the Royal University of Ireland in 1889. In the years that followed he built up a considerable practice in the city of his adoption, and became a prominent figure among his colleagues there. He developed and maintained a lively interest in professional affairs, more especially on the medico-political side. A Fellow of the Ulster Medical Society, he filled the office of librarian for many years.

To the British Medical Association Dr. Storey gave ungrudging service. He was elected honorary secretary of the Belfast Division in 1914, and held that office without a break until the time of his death; in the years 1915–18 he acted as representative of the Division in the Representative Body of the Association, and he had also served for seven years as a member of the Irish Committee. During the past eighteen months he visited headquarters in London from time to time as a member of the Propaganda Subcommittee.

A colleague writes: The untimely death of Dr. Storey has awakened widespread regret among the members of the medical profession in Belfast, by whom he was held in universal respect and esteem, both on account of his outstanding gifts and his high character. Although naturally of a modest and retiring disposition, he took an active part in the various medical organizations. His frequent contributions to the proceedings of the Ulster Medical Society were all carefully prepared, elegant in composition, and invariably illuminated by irresistible flashes of humour. It is, however, as secretary of the Belfast Division of the British Medical Association that he will be best and longest remembered. His labours on its behalf were unceasing and indefatigable. He carried on a perpetual propaganda for the enrolment of new members, and never ceased his efforts to interest his professional brethren in the important issues that came up for consideration by the Representative Body. He leaves behind him very fragrant memories and a vacant position which will not easily be filled. The regret at his death and the sympathy with his sorrowing relatives experienced in Belfast are shared by all those at the headquarters of the Association, who realized and appreciated his great services.

SIR DAVID SERJEANT, M.D.,

Camberwell.

WE have to announce the death of Sir David Serjeant, which occurred at his home in Camberwell on January 12th, a few days before the date on which he would have attained the age of 99.

David Maurice Serjeant was the son of a lawyer in Huntingdonshire, and was born at Ramsey in that county in January, 1830. While he was in his teens he was apprenticed to a Peterborough surgeon, but at the age of 22 he went to Australia, where, rejecting an offer of a position in the civil service, he decided to try his fortune in the gold-fields. Success did not attend his efforts, and he became successively gardener, painter, paperhanger, and lawyer's clerk in Melbourne—then in the early stages of its development—and played in the first two intercolonial cricket matches in Australia for Victoria against New South Wales. He was the last survivor of the teams. In 1859 he returned to England and resumed his medical studies at Guy's Hospital, graduating M.D.St. And. and obtaining the diploma M.R.C.S.Eng. in 1862 and the L.S.A. a year later. Serjeant afterwards spent several years in the medical service of the P. and O. line as a ship surgeon, ultimately settling down in Peckham Road, Camberwell, about sixty years ago, when he became medical superintendent of the infirmary now known as St. Giles's Hospital.

Apart from his professional duties Serjeant took an active part in the life of the district, and had held many public offices, having been a vestryman, a guardian of the poor, and a councillor and alderman of the borough of Camberwell. In politics he was a strong Conservative, and gave effective support to the local party organization; it is only two years since he made his last public speech at the Peckham Conservative Club. It was claimed on his behalf that he was the oldest Volunteer in the country, and he preserved his association with the auxiliary forces during the war, when he was medical officer to the Camberwell National Reserve. His knighthood was conferred upon him in 1922 in recognition of his public services in various spheres of activity.

Sir David Serjeant delighted in reminiscences of his early life, and often recalled his experiences in the days of the gold rush in Australia. He was particularly proud of the fact that he had played the first ball in the first intercolonial cricket match at Melbourne, then Port Phillip. The development of Camberwell, which he had watched in its growth from a wealthy semi-rural residential district to a closely built, densely populated area, was a continuous source of interest to him, and he had often described the striking changes in society and transport which occurred in his lifetime. It is significant of his affection for the district in which he laboured that he showed no desire to leave it when he retired. Until a few months ago he was a familiar figure in the neighbourhood, and it was in a street near his home, early last November, that he fractured his leg as the result of a fall, from the effects of which he never fully recovered. His wife died about twenty years ago; he had three daughters and one son, all of whom, with the exception of one daughter, entered the medical profession.

THOMAS EDWARD HOLMES, M.D., D.P.H.,

Medical Officer of Health for Nottinghamshire.

WE regret to have to announce that Dr. T. E. Holmes, medical officer of health for Nottinghamshire, died on December 24th, 1928, at the age of 52.

Thomas Edward Holmes received his medical education at the University of Cambridge and at Guy's Hospital, graduating B.Ch.Camb. in 1900, M.B. in 1901, and proceeding M.D. four years later. In 1909 he obtained the Diploma in Public Health of the English Conjoint Board. After serving as house-physician and ophthalmic house-surgeon at Guy's Hospital and as clinical assistant at the Evelina Hospital for Sick Children he was appointed assistant physician and pathologist to the Royal Hospital for Sick Children and Women at Bristol. Subsequently he entered the public health service on the staff of the Nottingham County Health Department, where he was employed successively as assistant and deputy to the medical officer of health before being himself appointed to that office, with the duties also of chief tuberculosis officer and school medical officer for the county, in 1925. During the war he held a temporary commission as major in the R.A.M.C. In the British Medical Association his main interest was in the scientific side, and at the Annual Meeting at Nottingham in 1926 he was vice-president of the Section of Public Health. He was a Fellow of the Royal Society of Medicine, of the Royal Sanitary Institute, and of the Society of Medical Officers of Health.

A colleague writes: Dr. Holmes witnessed great developments in public health work in Nottinghamshire. While he was cautious to a degree, once he was convinced that it was not in advance of public opinion, he did all he could to forward any new movement that he felt would benefit the community. He was anxious that public money should not be wasted, and in his department the spending of every penny was carefully watched. Unknown to many of his colleagues he suffered for years from a severe physical disability, and the courage and persistence with which he carried on to the end is an example to all. He had a

strong sense of the responsibility of his post, but to understand him it was necessary to see him off duty and in his own home. His sudden death is greatly regretted by all who came into contact with him. Dr. Holmes leaves a widow and one child.

THE LATE DR. F. W. TUNNICLIFFE.

DR. T. W. PRESTON, assistant physician to the Croydon General Hospital, writes:

Although only associated with the late Dr. F. W. Tunnicliffe in the capacity of a ward clerk at King's College Hospital, his personality imbued me with such deep respect that I crave space for these few lines of appreciation. As a teacher of therapeutics and practical medicine his place will be difficult to fill; as a physician he evoked my admiration from the first. He was a sound diagnostician; and, moreover, his interest, even in the most hopeless case, was not merely to conjecture the probable *post-mortem* findings, but to apply his knowledge of therapeutics for the patient's comfort and benefit. Although untiring in his efforts to teach any student who followed him round the wards, he always remembered that the occupants of the beds were living beings like himself, and that their interests must be his primary consideration—not only in the healing of their bodies, but in the avoidance of the wounding of their susceptibilities. Truly a man who, as a practical physician, is entitled to take his place among the highest.

Dr. JAMES MCLACHLAN, whose death occurred at his home at Lockerbie on December 18th, 1928, was a well-known practitioner in Annandale district. He had reached the age of 82 years, and had been ill for some time, but he had been able to continue active practice until about a year ago. A native of Rothesay, he received his medical education at Glasgow University, graduating M.B., C.M. in 1874. He was subsequently resident physician in Glasgow Royal Infirmary, and medical officer at Glamorganshire County Asylum. At the time of his retiral he had been engaged in practice for fifty-one years at Lockerbie, where he was widely known and held in the highest esteem. He was an active member of the British Medical Association, and took a prominent part in many local interests outside medicine. For many years Dr. McLachlan was an enthusiastic Volunteer, and had been surgeon colonel to the 3rd Volunteer Battalion, K.O.S.B., receiving the Volunteer Decoration for his services. He was a justice of the peace for Dumfriesshire, and was closely associated with several local lodges of Freemasons, Foresters, and others. The local nursing association found in him an active supporter, and he was for many years an elder in the United Free Church at Lockerbie. Dr. McLachlan is survived by a widow and a family of three sons and four daughters. He had been assisted for some years by one of his sons, Dr. Charles F. McLachlan, who carries on the practice.

The following well-known foreign medical men have recently died: Dr. GEORG SCHNEIDEMÜHL, emeritus extraordinary professor of comparative pathology at Kiel University, aged 75; Dr. FRANZ SCHMITT, professor of special pathology and treatment at Munich University; Dr. E. CHRISTELLER, extra-ordinary professor of morbid anatomy at Berlin; Professor C. FIRKET, a Berlin pathologist, aged 39; and Dr. EDWIN STANTON FAUST, a Baslo pharmacologist, aged 58.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

Pinsent-Darwin Studentship.

THE managers of the Pinsent-Darwin Studentship have appointed Dr. R. A. McCance of the Pathological Department of King's College Hospital, as student for a period of three years from February 1st, 1929.

The first Pinsent-Darwin student is Dr. R. D. Gillespie, whose principal topics of investigation during the past three years have been (*a*) the relationships of traits of personality to psychoneuroses, and (*b*) the criteria for the differentiation of types of depression. An examination of eighty psychoneurotic patients has shown some fairly definite relationships of personality-traits both to the general type of psychoneurosis developing and to the individual symptoms. Of the various criteria that have been examined for the differentiation of depressive conditions, the most serviceable prognostically and therapeutically is that of reactivity, in the sense of responsiveness to psychological factors of whatever kind. A complicated assortment of other criteria has been examined in thirty cases so far and the cases grouped accordingly.

A subsidiary investigation, on hypochondriacal reactions, has dealt with their nosological position and therapeutic accessibility; the results have recently appeared in the medical press, especially (in detail) in the *Guy's Hospital Reports*.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examination indicated:

D.P.H.—R. M. Jones, J. Litt, F. R. O'Sheil, J. T. C. Roberts.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on January 10th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

The diploma of Fellowship was granted to James Eastwood Sykes, and the diploma of Membership to M. K. Gyi, J. F. V. Lart, and B. W. Rycroft.

The following diplomas were granted jointly with the Royal College of Physicians:

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.—M. I. Ashmawi, A. Blagoff, N. M. Endie, M. Husnain, N. H. Meacle, H. V. O'Shea, H. M. Petty, S. Roy, E. C. Tamplin, W. L. Thomas.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—R. W. Armstrong, Eileen A. Chennell, A. Craig, H. Hinchco, Phyllis M. Horton, D. L. McCullough, D. Menzies, J. E. Nicole, Muriel L. M. Northcote, Evelcon J. O'Brien, J. C. Ramsay, C. E. Roachsmith.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the examination concluded on December 14th 168 candidates were examined, of whom 45 were approved and 123 rejected.

In pursuance of a report of the Board of Examiners in Anatomy and Physiology for the Fellowship, regarding the examination concluded on December 14th last, the Hallett Prize was awarded to Shantilal Jamnadas Mehta, M.B., B.S., of the Bombay University and Middlesex Hospital. The Hallett Prize was instituted as a tribute to the valuable services of Sir Frederick Hallett, late secretary of the Examining Board in England, during his fifty years' service with the College.

Following a report from the Examiners in Anatomy for the Fellowship, Clause 3, Subsection 3 of Section 3 of the Fellowship regulations was amended as follows:

Old Regulation.

3. Of having dissected at a recognized medical school or schools for a period of not less than six terms or eighteen months (Dissections during the regular vacations will be accepted provided that the certificate shows that they have been performed under the superintendence of an authorized teacher in a medical school.)

New Regulation.

3. Of having dissected at a recognized medical school or schools for a period of not less than sixty weeks. (Dissections during the regular vacations will be accepted up to a maximum of six weeks in any one year, provided that the certificate shows that they have been performed under the superintendence of an authorized teacher in a medical school.)

A letter was read from Dr. Ali Bey Ibrahim expressing appreciation of the honour conferred upon him by the grant of the honorary Fellowship of the College.

A letter was also read from Mr. Frank C. Madden, F.R.C.S., dean of the Faculty of Medicine, Cairo, reporting that the following resolution was adopted by the Faculty on December 6th:

That the congratulations of this Faculty Council be offered to Professor Ali Bey Ibrahim on his well-merited honour, and that the most cordial thanks of the Council be extended to the Council of the Royal College of Surgeons for the honour they had conferred on Professor Ali Bey and on this Faculty and their deep appreciation of this extraordinary mark of goodwill towards them on the part of the Royal College of Surgeons.

The President reported that he attended the centenary celebrations of the Faculty of Medicine, Cairo, held at Cairo from December 15th to 22nd last, and that he presented the diploma of the Honorary Fellowship to Dr. Ali Bey Ibrahim on that occasion. Sir Thomas Barlow was re-elected and Sir Anthony Bowlby was elected as members of the Executive Committee of the Imperial Cancer Research Fund. Mr. McAdam Eccles and Mr. Victor Bonney were appointed to assist the British Pharmacopœia Committee in deciding what articles or preparations in the last edition (1914) should be omitted from the next edition and what additions should be made to it.

Lectures.

In addition to the six Hunterian lectures by Sir Arthur Keith on the anatomy and evolution of the human brain, which we have already announced, the following lectures will be given at the College at 5 p.m. on the dates indicated:—January 28th—Professor Arthur Evans: Development of Diverticula; January 30th—Professor G. E. Gask: The Treatment of Malignant Disease by Radium, with demonstration of patients who have been treated; February 1st—Professor C. A. Pannett: Local Anæsthesia in the Surgery of the Upper Abdomen; February 4th—Professor R. J. McNeill Love: The Treatment of some Acute Abdominal Disorders; February 6th—Professor C. P. G. Wakeley: The Etiology, Pathology, and Treatment of Tumours of the Intestinal Tract; February 8th—Professor R. T. Payne: The Treatment of Varicose Veins and Varicose Ulcers by Injection; February 11th, 13th, and 15th—Professor H. A. Harris: Bone Growth in Health and Disease.

Medical News.

THE Hunterian Society of London will hold a banquet, to commemorate the two hundred and first anniversary of the birth of John Hunter, at the May Fair Hotel, Berkeley Street, W., on Thursday, February 14th, at 7.30 p.m. Communications should be addressed to Mr. W. E. Tanner, M.S., 38, Queen Anne Street, W.1.

THE annual dinner of past and present students of the Royal London Ophthalmic Hospital will be held at the Langham Hotel, Portland Place, on Thursday, February 7th, at 7 for 7.30 p.m., with Mr. Charles Howard Usher, F.R.C.S., in the chair. Early application for tickets (15s., without wine) should be made, enclosing remittance, to Sir William Lister, 24, Devonshire Place, W.1.

THE Eugenics Society will hold its Galton anniversary dinner on Saturday, February 16th, at 7.30 o'clock, at the Rembrandt Hotel, Brompton Road. The Galton Lecture, entitled "The coming of age of the society," will be given by Major Leonard Darwin, Sc.D.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Monday, January 21st, at 5 p.m., Dr. Robert Hutchison will lecture on "Pitfalls in the diagnosis of dyspepsia," at the Medical Society of London, 11, Chandos Street, Cavendish Square. On the same day at the Children's Clinic, Western General Dispensary, at 3 p.m., Dr. Bernard Myers will lecture on "The nervous child in our midst" (Cases); he will be assisted by Dr. Mackenzie Wallis, who will demonstrate the method of biochemical examination of the blood in neurotic children. Two demonstrations will be given on Wednesday, January 23rd, one at St. Mary's Hospital, at 2 p.m., by Mr. Zachary Cope, and the other at the Wellcome Museum of Medical Science, 33, Gordon Street, at 4 p.m., by Professor Hugh MacLean, on "The medical treatment of gastric and duodenal ulcer." On Thursday, January 24th, Dr. Gerald Slot will give a special lecture-demonstration, at 12.15 p.m., at the Royal Waterloo Hospital. There are no fees for attendance at the above lectures, etc. Two special courses begin in the following week, one opening at the Prince of Wales's Hospital, Tottenham, on Monday, January 28th, being a two weeks' intensive course in medicine, surgery, and the specialties; the second beginning on Tuesday, January 29th, a series of eight lecture-demonstrations in psychological medicine, to be given at the Bethlem Royal Hospital, at 11 a.m., on Tuesdays and Saturdays. Detailed syllabuses of these and of other special courses, and information on general post-graduate work, may be obtained of the secretary of the Fellowship, 1, Wimpole Street, London, W.1.

A POST-GRADUATE course on diseases of the nervous system will be held at the National Hospital, Queen Square, from January 28th to March 22nd, consisting of clinical lectures and demonstrations daily, except Wednesdays and Saturdays, at 3.30 p.m., teaching in the out-patient department daily, except Saturdays, at 2 p.m., and seven pathological lectures and demonstrations on Mondays, at 12 noon. Another course, comprising twelve clinical demonstrations, chiefly on methods of examination of the nervous system, will be given on Tuesdays and Thursdays, at 12 noon; and if there are sufficient applicants a course of eight lectures on the anatomy and physiology of the nervous system will be arranged on Fridays, at 12 noon. A limited number of students can be enrolled as ward clerks. Detailed information regarding fees, etc., for the above courses and for clerkships may be obtained from the secretary, Medical School, National Hospital, Queen Square, London, W.C.1.

THE Royal Society of Medicine has received from Lady Singer the generous gift of £500, in memory of the late Sir David Ferrier. Lady Singer, who has long been interested in the activities of the Royal Society of Medicine, was for some years associated with Sir David Ferrier in his work. The income from the gift, which is to be invested in trustee securities, will be devoted to the purchase of neurological books for the society's library, a form of memorial which will not only appeal to those interested in the same work as Sir David Ferrier, but which may be regarded as a step towards the endowment of the library of the Royal Society of Medicine.

THE *English Review* for January has an interesting paper by Sir Michael Sadler on the educational needs of England, and an unsigned article discussing the provisions of the Bill for Local Government Reform.

FOR the benefit of those who are obliged to consider their holiday arrangements early in the year, attention may be drawn to the medical study tours in Italy conducted by the State Tourist Department. Next year's tour will be held in September and will last seventeen days. The comfort of members is the subject of minute attention, and a special train is provided. Particulars may be obtained from the Ente Nazionale Industrie Turistiche, Via Marghera 6, Rome, or from the Italian Travel Bureau, 16, Waterloo Place, Regent Street, S.W.1.

WE have received a copy of the twenty-fifth anniversary number of the Handbook of the American Medical Association of Vienna, which gives details of the post-graduate courses and other forms of medical instruction available in that city during the next two years. Besides full accounts of the work possible in various clinics, useful information is provided about residence in Vienna, and the Handbook can be confidently recommended to any who wish to make use of these well-known teaching facilities. Inquiries should be addressed to the secretary of the American Medical Association of Vienna, Alserstrasse 9, Vienna.

ACCORDING to the New York correspondent of the *Times*, 2,647 new cases of influenza and 1,438 fresh cases of pneumonia were reported to the Department of Health in that city during the week ending January 12th. In the last seven weeks of 1928 it is estimated that some 26,000 deaths had occurred in the United States from influenza and pneumonia. On December 13th a bill was introduced into Congress appropriating a large sum to combat the epidemic.

AN international hospital congress, the first gathering of its kind, will assemble at Atlantic City, New Jersey, on June 13th. The object of the congress, as its name suggests, is to bring about the exchange of ideas among those concerned with the construction, organization, and administration of hospitals throughout the world. In connexion with the congress there is being arranged a valuable exhibit of plans and models of hospitals, of various types of equipment and supplies, and of statistical data relative to the care of the sick throughout the world. The congress will be followed immediately by the annual convention of the American Hospital Association.

AT a resumed inquest at Battersea on January 10th on Mrs. Doria Ruth Simmons, a Streatham woman teacher, who died in hospital on December 13th, 1928, the jury returned a verdict of manslaughter against Dr. Daniel Evans Powell, High Street, Tooting. Sir Bernard Spilsbury, in evidence, stated that death was due to abortion, septic infection, and inflammation of the kidneys. Dr. Powell was committed for trial by the coroner, Mr. Ingleby Oddie, and appeared before Mr. Broderick at the London South-Western Police Court on the day following, when the case was adjourned until Saturday, January 19th. Bail was allowed.

AN international congress on light treatment will be held in Paris from July 22nd to the 27th, 1929, under the presidency of Professor d'Arsonval. Papers will be read on the unit of measurement for the therapeutic use of ultra-violet rays; the treatment of tuberculous peritonitis by light; the prophylactic value of ultra-violet rays; and the treatment of rheumatic conditions by infra-red rays. There will be an exhibition of apparatus, and also one dealing with the history and progress of heliotherapy and phototherapy. An elementary course on actiotherapy will be given, and technical experiments will be demonstrated. The subscription for enrolment as a member of the congress, including the supply of a copy of the *Transactions*, is 16s. 6d. Further information may be obtained from Dr. W. Kerr Russell, 12, Park Crescent, Portland Place, W.1.

THE fourth meeting of the Permanent International Committee on Occupational Diseases will be held at the Faculty of Medicine in Lyons on April 3rd. Among subjects to be discussed are silicosis, cataract of occupational origin, and the endocrine system and poisoning, with, in addition, unpublished communications on questions relating to occupational diseases. The final programme will be drawn up when the titles and texts or summaries of these communications have been received. Participation in the meeting is open to titular members of the committee and to persons introduced by them, by the executive, or by the organizing committee; the subscription for persons from Great Britain is 20 gold francs, which entitles those attending, among other things, to travel on the French railways at half the ordinary fares. The meeting will end, after a series of visits to factories, on April 6th, when it is hoped to arrange an official banquet. Dr. Mazel, 54, Avenue de Noailles, Lyons, France, is the secretary of the organizing committee.

PROFESSOR LEOPOLD ARZT has recently been appointed editor of the *Wiener klinische Wochenschrift*.

THE following appointments have recently been made in foreign medical faculties: Dr. Kapfhammer of Leipzig, professor of physiology at Freiburg in Baden; Dr. George Hermann, professor of psychiatry in the German University at Prague, in succession to Professor O. Pötzl; and Dr. Otto Goetze, professor of surgery at Erlangen, in succession to Professor E. Graser.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF A MOLE.

"BETA" writes: Two years ago I removed from the neck of a girl, aged 18, a small mole, present from childhood, but which had recently grown slightly larger. Later, I noticed in the edge of the scar a minute pigmented speck, showing removal to have been incomplete. This speck remains stationary, of pin-point size. I should be glad of advice as to whether to do anything further or to leave it alone.

PAIN IN VARICOSE VEINS.

DR. DUNCAN GREIG (London, S.W.1) asks for advice as to the treatment of pain in varicose veins, especially as to the value of ultra-violet therapy in this condition. He states that one of his patients, a very tall man of gouty diathesis, has suffered more than twenty years from extensive and bilateral varicose veins, in which severe pains occur after slight exertion.

MUSCULAR CRAMPS IN ARTHRITIS.

DR. F. W. STANSFIELD (Reading) writes: In reply to "Alpha" (January 5th, p. 52), I would suggest that the patient may have a temperature which is habitually subnormal; this causes a deposition of sarcolactic acid in the muscles and nerve trunks. The remedy is to raise the body temperature either by physical means (hot baths, warm clothing, etc.) or by chemical means, or by both. I have found iodo-thiosinamin (iodo-lysin of Messrs. Allen and Hanburys) m xv after breakfast a convenient drug for this purpose. I raised my own temperature to 99°, or a little over, every evening for two months and cured the sciatica from which I suffered, as well as the secondary cramps. It is advisable, however, to begin with a smaller dose, since in patients who are saturated with rheumatism this amount given as an initial dose may cause a rigor. In some cases I have found even mij sufficient to begin with, this being gradually and cautiously increased. It is significant that "Alpha's" patient was free from cramps during an attack of lobar pneumonia, and for some weeks afterwards. The explanation may be that the pyrexia of pneumonia dissolved out the rheumatic poison for the time being.

INCOME TAX.

A Question of Assessment.

"P. Q." bought a practice last August and has been assessed on his earnings as assistant in another practice up to then *plus* a sum representing the amount at which his predecessor would have been assessed for the period August to April, 1929. Is this correct?

*** The assessment in respect of the assistant's remuneration is correct. As regards the practice it is not strictly correct to base the assessment on the predecessor's earnings; the proper basis of liability is "P. Q.'s" actual earnings for the period. But that amount must be calculated on a book debt basis and not on cash receipts, so that if the change has not adversely affected the practice "P. Q." may not feel that it is worth his while to dispute the existing assessment.

Expenses incurred by Assistant.

"C. F. K." inquires what will be the position with regard to his claim to deduct motor expenses incurred by him as assistant if his principal gives him an allowance in respect of petrol.

*** The claim will remain valid, but will be reduced by the amount of the petrol allowance.

LETTERS, NOTES, ETC.

℥ AND ʒ.

DR. JAMES FANNING (London, E.C.) writes: The report of a recent inquest draws attention to the close similarity of the signs in use for the fluid ounce and fluid drachm of the imperial measure of capacity, a similarity which I have always felt to be undesirable. I suggest that it is time to consider altering the sign of the fluid ounce so that it shall be quite distinctive, and the risk of further such fatalities may be lessened. On several occasions it has been my experience to find the two confused (fortunately never with serious results), and I have no doubt that this has also been the experience of others. This confusion is not necessarily the result of ignorance, but may very easily occur as a result of temporary aberration while writing or copying prescriptions, or, on the other hand, a prescription need be only moderately illegible to be read mistakenly.

CREOSOTE IN PNEUMONIA.

DR. W. H. LEWIS (Llansantffraid) writes: The case of rapid recovery from pneumonia recorded by Dr. S. M. Wells on January 5th (p. 15) prompts me to give my experience of the creosote treatment. During the influenza epidemic of 1918 I had lost two cases of pneumonia in young adults, when I read a letter in the *British Medical Journal* giving an account of the value of creosote in pneumonia. I tried the drug in my next case with most gratifying results, the signs and symptoms subsiding after thirty hours. I subsequently recorded forty cases without a death. I have had no fatal pneumonia cases since where treatment with creosote has commenced within the first twelve hours, and my confidence in it is so profound that, if I see a patient within the first twelve hours, I promise a normal temperature after thirty hours. It may be that the type of pneumococcus I have had to deal with is particularly susceptible to creosote, but certainly the last ten years of my practice have been free from anxiety as regards treatment for this dread disease, which so frequently terminates young and promising lives.

SUDDEN DEATH ASCRIBED TO SCARLET FEVER.

DR. A. GORDON WILSON (Thurlstone, near Sheffield) writes: May I suggest that the cause of the sudden death attributed to scarlet fever by Dr. F. Stanley Rose of Sunderland in your issue of January 12th (p. 88) was due to von Jaksch's anaemia. The enlarged spleen, the sex, the fact that the boy was a twin, the pallor of the intestines, are all in favour of the boy having a disease which is known to terminate fatally when the patient is attacked by diarrhoea and gastric disturbance.

PAINLESS LABOURS.

DR. S. M. WELLS (Valparaiso, Chile) writes: Following the cases of painless labours reported on October 27th, 1928 (p. 745), by Dr. Mary DeGaris, I would like to record a case in my practice some three years ago. A primipara, who had had a normal pregnancy in every respect, went to bed one night feeling perfectly well and slept until the early hours of the morning. She awoke with a desire to go the lavatory, and while there a lot of water came away. This alarmed her, and although she had no pain, I was called to see her. On my arrival she was perfectly comfortable in bed; I found the bag of waters had ruptured and the head was bulging the perineum. She had no pain at all, only an intermittent desire to go to stool. On being told to bear down when this desire came, a full-term child was born, without even a perineal tear, within half an hour of my arrival at the house. The puerperium was normal.

BRITISH INDUSTRIES FAIR.

THE British Industries Fair has been arranged for the second fortnight of February at the White City, London, and at Birmingham. An advance catalogue of the London section which has reached us has about the same weight and measurements as an average brick, and contains particulars of the exhibits of more than 1,200 manufacturers, all of them British, and all of them showing goods only of their own manufacture. The Fair thus becomes an extended shop window of British industry. Any medical man who happens to be interested in the commercial production of the material and equipment used in his practice will find much to interest him in the large sections devoted to medical and surgical appliances and instruments, drugs and pharmaceutical preparations, x-ray and electro-medical apparatus, and laboratory and hospital fittings and ware. It is pleasant to learn to how small an extent we need depend upon the foreign manufacturer, and how versatile and enterprising are our own countrymen. An interesting feature of the catalogue is that all the goods are indexed in nine languages.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 46, 47, 48, 49, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 19.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

60. Bread-making as a Cause of Disease.

ELISABETH KRÜGER and E. SAUPE (*Med. Klinik*, November 30th, 1928, p. 1860) have contrasted the clinical appearances of thirty-three bakers and twenty-five millers. The pallor of the skin observable in all the cases is probably associated with indoor life, since in only six was the haemoglobin percentage under 90, and the minimum was only 70. In both classes slight conjunctivitis and pharyngitis was common, and in many the teeth were defective, owing possibly to the destructive action of the acids produced by the flour dust. The cardiac findings were unimportant: one baker had aortic aneurysm with aortic insufficiency; systolic murmurs were heard only in three cases. Blood pressures were high, but this was correlated with the comparatively advanced age of those that were examined. Twenty-six of the thirty-three bakers and ten of the twenty-five millers had flat-foot, and knock-knee was fairly common. Acne due to moisture and sweat was noted in many cases: scabies and nail disease, so prevalent among confectioners, was not met with. The elder bakers not infrequently had callosities on the ulnar side of the little finger. Among the millers fifteen had "millers' itch"—greyish-black patches on the hands and dorsal and radial aspects of the lower forearms, due to the action of small steel splinters and particles of stone detached while sharpening the millstone—and were well exhibited in *x*-ray pictures. The chests of both classes were more or less barrel-shaped, and scoliosis was found in fourteen bakers and twelve millers. Contrasting the *x*-ray pictures of the lungs, it was noted that the lungs of millers were more congested than the lungs of bakers, which the authors consider is caused by the frequent inhalation by millers of fine steel particles, impure flour dust, spelt, and grains of chalk, producing irritation and hyperaemia of the bronchial mucous membrane, resulting clinically in chronic bronchitis. Bakers are exposed to coal dust and ash dust, and suffer from slight pneumoconiosis with thickening of the interacinous connective tissue. Dry bronchitis was present in twelve bakers and in ten millers. The sputum occasionally showed particles of flour; tubercle bacilli were not detected in any case.

61. Lead Poisoning in Bronze Foundries.

F. G. PEDLEY and G. SPROULE (*Canadian Med. Assoc. Journ.*, November, 1928, p. 566) consider that the occurrence of lead poisoning in bronze founders cannot be very uncommon, and they record their observations upon ten patients with symptoms typical of plumbism: the blue line on the gums, stippling of the red blood cells, lead in the urine, and complaining of severe abdominal pain and constipation. No patient had any paralyses, and most were able eventually to return to work after treatment and diet. From experimental considerations and from observations in a foundry the authors found that 4.5 grams of lead are discharged into the atmosphere of the casting rooms in the six minutes required to dispose of 350 pounds of alloy, while the maximum daily dose allowable to be inhaled is 1 mg. of lead per day. They state that adequate ventilation is the main prophylactic, and that with a plenum system the air should be delivered at about the head level in various parts of the room, being chiefly concentrated about the moulds; the furnaces should be equipped with hoods connected with exhaust fans. Since some workers are more susceptible to lead poisoning than others, there should be periodical weekly medical examinations, and milk should be supplied. Provision should be made for washing and for meals to be taken away from the moulding room; smoking and chewing while at work should be forbidden.

62. Typhoid Septicaemia.

J. CHALIER and J. ROUSSET (*Lyon Méd.*, October 21st, 1928, p. 487) describe the case of a woman, aged 36 years, who was admitted to a fever hospital with a diagnosis of enteric fever. The serum reaction was positive. The patient and her three children had always been healthy. She had been taken ill suddenly, four days before admission, with lumbar pain, followed by frequent vomiting and, subsequently, diarrhoea. Two days later her temperature was 104° F.; she had rigors and severe headache. On admission her temperature was 104.7°; the tongue was dry and the bowels were constipated; the abdomen was slightly distended and showed no rose spots; the liver and spleen were enlarged. There was no delirium. In a few days the patient became deeply jaundiced; her temperature remained between 103° and 104° F. until her death a week after admission. At the necropsy the lungs were found to be slightly oedematous, but the heart was normal. The liver was enormously enlarged, weighing 5 lb. 14 oz.; its surface was studded with miliary abscesses, and on section similar deeper abscesses were found. The gall-bladder was normal. The spleen was very large, weighing 15.6 oz., but appeared otherwise normal. The right kidney was also normal. The left kidney was very enlarged and contained many small abscesses similar to those in the liver. The authors comment on the surprising fact that the intestines appeared to be normal. Pus from various abscesses yielded pure cultures of *B. typhosus*, and the condition was therefore undoubtedly typhoid septicaemia.

63. Immunization against Tuberculosis.

L. TOMARKIN (*Ind. Med. Record*, October, 1928, p. 288) discusses the problem of immunity with special reference to tuberculosis, and suggests a biological treatment for tuberculous toxaemia based on the view that toxins contain a crystalloid toxic principle resembling an alkali, together with a colloidal endo-enzyme having immunological properties; the first of these is readily eliminated through the kidneys, while the latter diffuses more slowly and accumulates in the body, becoming manifest as antibodies. By a complex biochemical and electrical process in five steps it is possible to split the toxin molecule into the two fractions, using the colloid as an agent for passive immunity. This substance, obtained by Tomarkin from tuberculin and called "catalysan," is thought to be the active antitoxic fraction in a pure state; it is an amorphous, brownish-yellow powder, insoluble in alcohol or ether, but soluble in distilled water to form a clear, slightly opalescent neutral solution. The colloidal endo-enzyme derived from tuberculin is stated to have acted beneficially when injected into patients with tuberculous toxaemia.

64. Diabetes Insipidus in Epidemic Encephalitis.

E. LEDOUX (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 15th, 1928, p. 1502), who reports an illustrative case in a man aged 20, states that all the cases of diabetes insipidus occurring during or after epidemic encephalitis present the same clinical picture, the polyuria being almost invariably the sequel of choreic and myoclonic manifestations. The disturbance of urinary metabolism in encephalitis may assume various forms. As a rule there is polyuria with polydipsia, which, however, may occur without polyuria, but also the amount of urine, instead of being increased, may be extremely reduced with or without a tendency to oedema. The present case was remarkable for the fact that the symptoms subsided on inhalation of powdered extract of the posterior lobe of the pituitary gland.

Surgery.

65. Haematuria in Surgical Diagnosis.

V. BLUM (*Wien. klin. Woch.*, December 6th, 1928, p. 1683) describes the various kinds of haematuria, the means of determining their origin, and how they may be treated. The haemorrhage may occur only at the commencement of micturition, when it is derived from the urethra; it may appear only at the termination of micturition, when it originates in the neighbourhood of the neck of the bladder, as in acute haemorrhagic cystitis, purpura, stone, foreign bodies, and small tumours. When the haemorrhage is derived from the prostate it is both initial and terminal. When the urine is uniformly mixed with blood this may be continual or intermittent; the blood may be detected only after a microscopical examination of the sediment. The urine may be bright red owing to the presence of fresh blood, may contain blood clots, or may only be brown-coloured. The presence of large clots suggests new growth of the kidney or kidney pelvis; when this is associated with large amounts of albumin, and granular, epithelial, and blood casts, the diagnosis points to haemorrhagic nephritis; if the haemorrhage is unilateral and accompanied by renal colic the presence of stone in the pelvis or ureter is suggested, and may be confirmed by an *x*-ray examination, the ureteral catheter, and a pyelograph. Unilateral renal haemorrhage in young subjects, associated with pus, is an indication of a tuberculous kidney, which may be confirmed by animal experiment. Unilateral or bilateral renal haemorrhage, with palpable tumour in the region of the kidney, raised blood pressure, swelling of the liver, and negative bacteriological and *x*-ray

findings, suggests the diagnosis of cystic kidney. Massive haemorrhage, with large amounts of clotting, occurs with tumours of kidney or pelvis, angioma, varix, acute and chronic nephritis, and renal infarcts. The site and origin of haemorrhage from the bladder, when severe, are revealed by catheterization and aspiration of the clots, followed by cystoscopic examination; if the bleeding is so profuse as to threaten a dangerous anaemia the bladder should be opened, the blood mass removed, and the site of the haemorrhage cauterized. The various sources of urethral haemorrhage are described. The author points to the necessity of estimating the quantity of blood in the urine, and of excluding other colouring matters, such as chrysophanic acid, which may give the appearance of haematuria. Generally treatment consists in rest in bed, application of cold, the administration of sodium carbonate, ergot, and calcium preparations; anaemia is combated by transfusion, the injection of saline, and unless otherwise contraindicated, by an operation such as nephrectomy, nephrotomy, decapsulation, or removal of stone. In cases of acute haemorrhagic cystitis a permanent catheter should be introduced and the bladder be washed frequently.

Inguinal Herniorrhaphy.

66. E. M. HODGKINS (*Surg., Gynecol. and Obstet.*, December, 1928, p. 831) advocates a modification of inguinal herniorrhaphy with living fascial sutures obtained from the rectus sheath for the construction of a firm barrier against recurrence. The steps of the operation are described; the skin incision and exposure of the canal are described so that the entire width of the sheaths of the recti is exposed, and the fasciae of the external and internal oblique muscles are disturbed as little as possible. The middle of the sac is transfixed by a suture, which is tied on one side and then wrapped round to be tied on the opposite side, both ends being left long. The excess of sac is amputated, and a few stitches are passed over the cut end to render its closure more secure. The ends of the suture on the sac are passed through a small opening in the internal oblique muscle and are carried upwards on needles through the medial leaf of the external oblique aponeurosis; the stump is fixed beneath this fascial layer. Attached sutures cut in the direction of its fibres are reflected from the rectus sheath to form fascial strips; the technique of weaving these into place is fully described. It is claimed that such sutures are adequate in length and tensile strength. By not being detached they are preserved living, and are bathed in normal lymph even during the operation; since there is no tension or constriction, no muscle necrosis is caused.

Duodenal Diverticula.

67. R. C. PENDERGRASS (*Amer. Journ. Surg.*, November, 1928, p. 491) defines diverticula of the duodenum as pouches or pockets arising from the duodenal wall and having a free communication with the duodenal lumen. Diagnosis from cholecystitis, duodenal ulcer, or duodenitis is difficult, and *x*-ray examination of the gastro intestinal tract furnishes the best means of reaching a correct conclusion. Careful fluoroscopic observations and oblique visualization of the duodenal loop are essential procedures in this examination. In all cases showing symptoms of some morbid condition in the upper abdomen the possible existence of a diverticulum of the duodenum should be borne in mind. If such a lesion is found to be present the decision must be made whether it is responsible for the symptoms noted or whether it is only an anatomical anomaly. In the former case, if the symptoms need early relief, operative treatment is indicated, which should be the ligaturing and excision of the diverticulum, with invagination of the base and suturing. If medical treatment is adopted it should be founded on that for duodenal ulcer; any diet securing alkalinization with little gas is helpful, and belladonna is indicated if there is spasm of the pylorus or duodenum. In cases showing definite clinical and *x*-ray evidence of colonic stasis, treatment of this condition will relieve the upper abdominal symptoms, thus indicating that the diverticulum, though present, may not be responsible for the symptoms.

Resection in Rectal Carcinoma.

68. K. STÖGER (*Deut. Zeit. f. Chir.*, November, 1928, p. 232) compares the immediate and ultimate results of various operations performed in 303 cases of rectal carcinoma during the period 1889–1922. He favours preservation of the sphincters, since colotomy, or the sacral anus left by Kraske's operation, are difficult to keep clean, frequently causing much mental distress. The chief objection to rectal resection, with preservation of the sphincters, is that fistulae occur frequently after the operation; this complication has caused some surgeons to abandon resection in favour of excision combined with sigmoid colotomy. In the author's series of 303 cases Kraske's operation was performed on 113 patients, with a primary death rate of 7.1 per cent. and 24.8 per cent. of recoveries. Death from recurrence accounted for 53.1 per cent. The best results followed rectal resection (76 cases). Although the primary death rate (15.8 per cent.) was more than double that following Kraske's operation, the ultimate recoveries were 44.8 per cent. Of the 34 patients who were cured, 8 were in good health after ten years, and 4 after twenty years, with normal function of the rectum. Stöger believes that this is the ideal operation for rectal carcinoma, since 80 per cent. of the patients who survived operation were cured. The difficulty arising, in many cases, from subsequent occurrence of fistulae can be overcome by excision and suture with flaps from the gluteal region. He has only employed Kirschner's operation as a routine method since 1924; therefore the results are not comparable with those of other operations, and they have not been included. Although abdomino-sacral excision permits a thorough examination of the peritoneum and abdominal viscera, together with the removal of retroperitoneal metastases as in Wertheim's operation for uterine carcinoma, the immediate mortality is very grave—33.3 per cent., while the ultimate recoveries were 35.1 per cent.—that is, 9.7 per cent. less than the recoveries from resection. Stöger performed abdomino-sacral excision only in the worst cases.

Therapeutics.

Trichlorethylene in Trigeminal Neuralgia.

69. I. OLJENICK (*Journ. Amer. Med. Assoc.*, October 13th, 1928, p. 1085) discusses the difficulties in the diagnosis of trigeminal neuralgia, and its usual treatment by ondoneural alcohol injections and avulsion of the sensory roots. During the late war certain symptoms were noted in men whose work involved the use of trichlorethylene and trichlorethane; among these were a slight swelling of the optic disc and particularly anaesthesia of the trigeminal area, the motor part of the nerve showing no alteration. Hearing of this elective action of the drug for the fifth nerve, Oppenheim tried inhalations of it in trigeminal neuralgia, with encouraging results in the first twelve cases. Oljenick states that this drug is now used at the University Hospital of Amsterdam in all cases of trigeminal neuralgia, but chemically pure trichlorethylene must be employed; this is a very strong-smelling liquid with the sweet odour of prussic acid. Giddiness and unconsciousness have followed its administration, so patients should be recumbent while inhaling it. Periods of exaltation may occasionally be observed, and sometimes pricking sensations in the hands and feet; these symptoms, however, disappear quickly. The author adds that, though it is not known why trichlorethylene has this elective affinity for the fifth nerve, it has been proved that the sensitiveness of the irritated nerve decreases after repeated inhalation. The method of treatment is to pour twenty to twenty-five drops of the drug on a small piece of gauze and inhale through the nose until the odour has completely disappeared; this should be done thrice daily. Care should be taken not to touch the nose with the liquid. From the Amsterdam results Oljenick concludes that in a comparatively small number of cases the inhalation of trichlorethylene, continued for some time, gives excellent and lasting results. In some cases the period of relief may be interrupted by renewed attacks, which usually are less violent than before. In most cases this treatment is a useful temporizing measure which, by diminishing the number and vehemence of the attacks, allows the patient's general and local condition to improve. He adds that since the pain is only rarely uninfluenced by trichlorethylene, it should be tried in every case; furthermore, as it has no effect on other facial neuralgias, it may occasionally be of value in differential diagnosis.

Therapeutic Measures in Arthritis.

70. FOR the treatment of acute and chronic arthritis F. KÜLBS (*Med. Klinik*, October 12th, 1928, p. 1575) recommends early movement with the use of hot air and morphine to control the pain. Acute articular rheumatism yields usually to salicylates, but the dosage must be sufficiently large and long-continued. In long illnesses the skin should be treated, either by rubbing soap in and leaving it on for at least an hour before washing off with hot water, or by prolonged hot baths, three to six hours daily. Acute polyarthritis may be complicated by meningitis. Külbs records a case in which lumbar puncture and the withdrawal of 40 c.cm. of cerebro-spinal fluid was followed by great improvement in the arthritis. In rheumatic purpura arsenic or salvarsan gives good results, and in erythema nodosum arsenic. Acute arthritis may develop not only with the acute infection, but with syphilis; such cases are difficult to diagnose and very important, as the treatment is that for syphilis, and while the blood Wassermann reaction may be negative, that of the joint effusion may be positive. There are two forms of chronic arthritis—polyarthritis and arthritis deformans; the first

comes on gradually, is resistant to treatment, and is difficult to distinguish from gout. In such cases colchicum is invaluable, also local measures such as hot air, hot sand baths, hot compresses made of a rubber sponge wrung out of very hot water, covered with gutta-percha tissue and thick flannel, renewed every fifteen to twenty minutes, and given three or four times in the forenoon and afternoon. Quick results follow injection of the patient's own blood into the joint capsule, the amount necessary varying with the duration and intensity of the illness and the size of the joint; as much as possible should always be given—for example, for the knee 20 to 40 c.cm. The syringe should be warmed and the piston smeared with glycerin. Sterile solutions of atophan or iodine may be used. The tonsils should be watched, and if necessary treated. Intravenous protein injections are a good adjuvant to other lines of treatment, also intramuscular injections combined with those of the patient's blood. Sun and radium baths may be helpful in chronic cases, probably because of their action on the skin. In every case individual attention for each patient, and the employment of energetic, systematic treatment, is of more importance than drugs given by the mouth.

71. Anti-coli-bacillary Serotherapy.

H. VINCENT (*Bull. de l'Acad. de Med.*, November 27th, 1928, p. 1232) recalls that there is no one particular type of *B. coli*; many atypical forms exist, termed para-coli or coliform bacilli. All these organisms possess the common characteristic of originating identical toxins—namely, a neurotropic exotoxin, causing coma and paralysis, and an enterotropic endotoxin, producing profuse diarrhoea and anatomical lesions of the epithelium of the small intestine. *B. coli* can be the agent in various acute or chronic infections, and no organ or tissue escapes its invasion. Vincent states that an antiserum has brought about rapid cures in cases of coli-bacillary septicaemia and acute and chronic suppurative pyelonephritis. It has also proved of great benefit after operations for gangrenous appendicitis in preventing general infection. Combined with multivalent antigangrenous serum it is a valuable adjunct in rendering the sequels of these conditions benign and simple. One of the most frequent and often grave effects of coli-bacillosis is suppurative pyelonephritis, which may complicate very different morbid states such as infections (influenza and typhoid fever), mechanical states such as *faecal stasis, entero-hepatic conditions*, and pregnancy. Primary suppurative pyelonephritis offers a great field for serum therapy. In many secondary cases due to conditions needing surgical intervention the serum acts only as a palliative; but in these cases also, in prophylactic doses, it is useful in preventing post-operative general infection. Where cure by the serum is incomplete or protracted, search should be made for lesions of the kidneys or bladder. The serum has been used with great benefit in the pyelonephritis of pregnancy. In mixed infections due to the association of other bacteria the serum has given remarkable results, and appears to have a marked specificity. Cure has sometimes followed serum therapy in chronic conditions and in carriers; in these cases especially disinfection of the renal pelvis and bladder should be employed simultaneously. Vincent emphasizes the need of instituting treatment as soon as the diagnosis is made.

Disease in Childhood.

72. Infantile Acrodynia.

M. PÉHU and R. CORREARD (*Arch. de med., cir. y esp.*, November 24th, 1928, p. 579 states that this condition, which has been variously denominated erythroedema (Swift), pink disease (Clubbe), dermato-polyneuritis (Thursfield), and neurosis of the neuro-vegetative system (Feer), is met with in children between the ages of 4 months and 5 years, and occasionally in adults. Clinically all the manifestations may be explained by an affection of the vegetative nervous system. The initial symptoms are those of vagotonia—namely, depression, profuse sweating, salivation, alternation of erythema and cyanosis of the extremities, and urticaria. In addition to these vagotonic signs, the insomnia, tremor, hypertension, and tachycardia may be traced to sympathicotonia. This disturbance of the vegetative nervous system may be attributed to an affection of the sympathetic centre in the mesencephalon. The authors regard acrodynia as an infectious disease, with its portal of entry probably in the nasopharynx; it is only slightly contagious and is closely related with epidemic encephalitis and poliomyelitis. There is no specific treatment. Many drugs have been recommended, such as quinine, calcium lactate, and thyroid or thymus extract. Feer has used atropine in fairly large doses and obtained satisfactory results, and Sweet has been very successful with ultra-violet rays. The authors consider that fresh air, good food, and hydrotherapy, combined with exposure to ultra-violet rays and injections of uroformin, constitute the best treatment.

73. Dieting of Newly Weaned Infants.

CLARA M. DAVIS (*Amer. Journ. Dis. Child.*, October, 1928, p. 651) reports an experiment on three newly weaned infants who were allowed to choose their own foods. The foods used included meat muscle, glandular organs, haddock, cereals, bone marrow and jelly, eggs, raw and lactic milk, fruits, vegetables, and sea salt. These foods were spread over three (in the early weeks, four) meals a day, both raw and lactic milk, animal proteins, and either fruits or vegetables being served at each meal. The preparation of the foods was as simple as possible: they were presented minced or ground, raw and cooked. The infant was permitted to eat in any way he could, or was fed from any dish he reached for or pointed to. There was no clue as to what influenced these infants in choosing the foods they tried first; occasionally they ejected what they had taken into their mouths. After the first few meals, however, the foods wanted were promptly recognized and chosen. All the infants showed themselves to be omnivorous, but with decided preferences. A tendency was observed in all to take certain foods—such as cereals, eggs, meats, or fruits—in waves, the quantity eaten each day rising gradually over a period of a week or longer to a maximum—seven eggs at a meal, for example, or four bananas—and then gradually declining to the previous level. No clear preference between raw and cooked foods was shown. The calorie value of the daily intake ranged between fairly wide limits. Appetite was uniformly good. There was no abdominal discomfort, diarrhoea, or constipation. From the standpoint of nutrition the immediate results appeared to be equal at least to the best results obtained by commonly prescribed diets. Two of the infants remained on this diet for six months and one for twelve months.

74. Non-tuberculous Cervico-thoracic Lymphadenitis in Children.

ACCORDING to R. COURTOIS (*Bruxelles-Médical*, October 21st, 1928, p. 1682) the tuberculin cutaneous reaction shows that in children non-tuberculous lymphadenitis occurs very frequently, and antituberculosis treatment should be combined with that of the probable causal infection. The author, who has used the tuberculin cutaneous reaction in 173 children, agrees with other writers that a positive reaction does not indicate that the patient has an active tuberculous lesion, but rather that there is a recent or old tuberculous focus. Courtois cites authorities in support of the view that chronic lymphadenitis in children is very frequently due to simple non-tuberculous infections, such as measles, scarlet fever, and whooping-cough. Among the 173 children examined 128 had lymphadenitis: in 47 children the cervical lymph nodes alone were involved, in 14 cases the tracheo-bronchial glands only were infected, while in 67 children there was cervical and tracheo-bronchial lymphadenitis. Among these 128 children only 57 had a positive cutaneous reaction; more than 55 per cent. had negative reactions and suffered therefore from simple non-tuberculous lymphadenitis. He adds that it does not follow that the remaining 44 per cent. who showed a positive reaction had a tuberculous infection, but rather that these patients are susceptible if exposed to infection. Courtois concludes that the site of infection must be treated rationally—that is, bacterial proliferation should be arrested; further infection should be prevented and the neutralization of toxins be promoted. He recommends that these patients should be sent to a "preventorium" where the children are under constant observation and the various infections can be attacked most successfully.

Obstetrics and Gynaecology.

75. Controllable Spinal Anaesthesia in Obstetrics.

G. P. PITKIN and F. C. MCCORMACK (*Surg., Gynecol. and Obstet.*, November, 1928, p. 713) advocate controllable spinal anaesthesia in obstetrics by the injection of a solution of novocain and gliadin (the mucilaginous content of wheat starch) into the subarachnoid space to produce caudal anaesthesia. With the head of the delivery table raised from 15 to 20 degrees so that the patient is in a slightly reversed Trendelenburg position, the puncture is made at the interspace between the fourth and fifth lumbar vertebrae, and after aspirating one or two drops of spinal fluid, a solution containing novocain, gliadin solution, strychnine sulphate, glucose, and normal saline solution is injected through the centre of a wheal raised at the site of puncture with novocain-ephedrine solution. Complete anaesthesia results in from one to three minutes, and becomes permanent in from ten to twelve minutes in over 99 per cent. of cases. By this

means only the sacral nerves are anaesthetized, producing a typical saddle anaesthesia, limited in front by the symphysis and extending over the lower part of the sacrum and down the inner side of the thighs for about six inches without any impairment of motion or anaesthesia of the legs. The cervix, vagina, perineum, vulva, and anal and bladder sphincters are completely anaesthetized, but sensation of the uterus remains. The patient may be recumbent or be placed in stirrups, provided the reverse Trendelenburg position of from 15 to 20 degrees is maintained. The advantages claimed for this procedure are that it is much safer than ordinary spinal anaesthesia and as safe as caudal anaesthesia; there is no shock or drop in blood pressure; the child is better protected than with any other form of anaesthesia; and there are no post-anaesthetic complications. The anaesthesia may be confined to the perineum or carried to any desired height, and it can be administered to patients for whom general anaesthesia is contraindicated.

76. Lipiodol in Gynaecological Diagnosis.

C. BÉCLÈRE (*La Gynécol.*, August, 1928, p. 477), from experience of one hundred cases, is convinced that intrauterine injection of lipiodol is of great utility in gynaecological diagnosis and treatment. The position and form of the uterus can be recognized; tubal patency can be assessed, and, therefore, feminine sterility be treated. Lipiodol is considered the best substance to employ, being very opaque, non-irritant, and antiseptic. In cases of obliteration of the abdominal ostium, division of adhesions or salpingostomy is indicated; isthmic or interstitial non-patency can be treated by excision of the obstructed zone and implantation of the pervious portion of the tubes into the cavum uteri—an operation which Cotte has performed in twelve cases, in six of which tubal patency was subsequently demonstrated. In a certain number of cases utero-tubal injections of lipiodol have been followed by pregnancy. P. MOCQUOT (ibid., p. 478) emphasizes the value of lipiodol injections in diagnosis of carcinoma of the corpus uteri, and in three cases has made this diagnosis without biopsy, but with subsequent operative confirmation. The shadows cast by the lipiodol are extremely irregular, in contrast with those given by fibroid polypi; hyperplastic endometritis causes scarcely any deformity of the cavum uteri.

77. Extrauterine Pregnancy.

E. BAMBERGER (*Zentralbl. f. Gynäk.*, November 24th, 1928, p. 3009) states that operations for extrauterine pregnancy at Mannheim have more than doubled since 1924. A similar progressive increase has been reported from more than one German clinic, and it seems likely that this is due in part to the fact that abortions, usually criminally induced, have been in late years relatively more frequent in young women, and in part to more general use of contraceptive measures, of which the favourite at present seems to be intrauterine injections of fluid after coitus. Of 150 ectopic pregnancies treated during the last four and a half years nearly one-half were in women aged less than 30, and 63 confessed to one or more antecedent abortions. In diagnosis of ectopic pregnancy reliance is placed chiefly on a careful taking of the case-history and on estimation of the sedimentation time of the erythrocytes. Pyrexia up to 100.5° or even 102° is not uncommonly encountered. Exploratory puncture of the posterior fornix, being thought to impair post-operative convalescence, is little used. The mortality was 3.3 per cent., and in cases with extensive intra-abdominal haemorrhage the infused blood, after mixture with citrate solution and the passage of oxygen through it, is reinjected into a vein of the arm.

78. Heart Disease in Pregnancy.

L. TRIAS DE BES (*Rev. Med. de Barcelona*, October, 1928, p. 329) records his observations on 47 cases of heart disease associated with pregnancy which he has observed during the last two years. The lesions were as follows: mitral stenosis 26 cases, aortic incompetence 5 cases, mitral incompetence 10 cases, mixed lesions 3 cases, active endocarditis 3 cases. In 19 of the cases of mitral stenosis, symptoms of cardiac incompetence, such as dyspnoea on exertion and palpitation, developed within the first few months of pregnancy, before the increase in the amount of blood or the size of the gravid uterus could interfere with the work of the heart, and were probably due to metabolic changes and especially to disturbance of the function of certain endocrine glands (thyroid, parathyroid, and suprarenals). The author maintains that pregnancy should not be permitted to occur whenever there is more or less marked evidence of cardiac inefficiency, or whenever, in the absence of obvious signs, its latency is suspected owing to its occurrence in a previous pregnancy. In the presence of an active endomyocardial process pregnancy should also be forbidden.

Pathology.

79. The Nature of Pernicious Anaemia.

J. H. MEANS and W. RICHARDSON (*Journ. Amer. Med. Assoc.*, September 29th, 1928, p. 923) discuss the physiological and pharmacological effects of liver administration in pernicious anaemia, and conclude that it is clear that deficiency of a specific hepatic substance is the cause of the derangements in this disease. The isolation by Cohn of such a body gives additional proof to this conclusion. The disease is clearly not an avitaminosis like scurvy or beri-beri; it seems more probable that there must be an acquired or hereditary defect in the individual, as well as a dietary error, for the production of the disease. The specific substance is found in mammalian liver and kidney, and apparently also in avian liver. It is unknown whether the individual usually manufactures the whole or part of the needed amount of the specific substance, or derives it wholly from his food; it cannot be regarded as an internal secretion of the liver, since it occurs in nearly as great concentration in a tissue so different as the kidney. Castle, working on the theory that the well-known achylia plays a part in the genesis of the disease, found that a response, similar to that produced by liver feeding, could be elicited by feeding skeletal muscle previously digested in a normal human stomach. The supply of this substance can be rendered adequate in patients by supplying them with large quantities of natural foods which contain it, or active fractions thereof, or perhaps also through the provision of means for normal gastric digestion. Shortage of the substance is clearly responsible for the abnormalities in the marrow and blood. Castle's work suggests that the gastric defect may be an important cause of the shortage. Whether the normal subject requires any extraneous supply of the specific substance or can synthesize what he needs is not known, nor whether the active substance now found is in the state that the body needs or is merely a necessary intermediate stage.

80. The Importance of Spirochaetes in Human Pathology.

J. BACIGALUPO (*C. R. Soc. de Biologie*, November 30th, 1928, p. 1622) draws attention to the frequency with which spirochaetes are encountered in cases of suppuration. In 1927, under the name of *Treponema uretritis*, he denoted a variety which he found in the urethra of a man who was suffering from a chronic discharge. In this case no gonococci could be detected in repeated examinations, and the Wassermann reaction was negative. The spirochaetes ranged from about 10 to 23μ in length, the average length being about 14μ. Cultures remained sterile, and animal inoculations were without any definite result. Intravenous injections of novarsenobenzol were without effect, but after a week's local irrigation with 1 per cent. and later with 10 per cent. solutions of this preparation, the discharge cleared up completely. The author has observed four cases of suppuration associated with the presence of Vincent's spirillum and fusiform bacilli, in which local treatment with novar-enobenzol has brought about a cure. He finds spirochaetes almost constantly in the haemorrhagic sputa of tuberculous and also of non-tuberculous patients, and he has been able to cultivate them on haemoglobin media. He regards them as responsible for the haemorrhages. Finally, he has observed spirochaetes in condylomata, and has obtained some successful results by local injections of novarsenobenzol.

81. Experimental Tar Cancer.

G. A. K. VON DEM BORNE (*Nederl. Tijdschr. v. Geneesk.*, November 17th, 1928, p. 5689) states that, with Lignac, he had previously shown (*ibid.*, 1927, ii, 1302; 1928, ii, p. 3534) that trypan blue affects the growth of an inoculated tumour (1) by considerably increasing the susceptibility of the organism to the transplanted growth, and (2) by the influence of the trypan blue on the transplanted tumour, as shown by an initial diminution in the "virulence" of the tumour cells. The relative proportion of these influences will determine the progress of the growth. It was found experimentally that when mice which had been painted with trypan blue were inoculated with sarcoma there was a much better and more rapid growth of the tumour than under other conditions. The author now describes experiments on white mice in which the skin of the back had been painted with trypan blue and afterwards with tar. It was found that, even after thirty applications of tar in the course of twenty-seven weeks, there was not a trace of blastoma formation detected, but the skin, on the other hand, became extremely atrophic and the corium hyperkeratinized. A large number of further experiments will be required before it can be proved that tumour formation can be effected by tarring mice which have been painted blue.

More Than an Evacuant

THERE are plenty of remedies that will clear out the bowels, but the all-important property that makes Agarol Brand Compound different from ordinary laxatives, is that its dose can usually be gradually decreased, and in many instances stopped entirely. This is the logical outcome of the physiological character of its action. Repeated regularly for a reasonable period, it trains the intestinal muscles, and thus restores their inherent powers—the "reflex sense," or ability to respond to stimuli—to a point where the bowels can perform their functions naturally and unaided.

In Agarol Brand Compound the practitioner has that long sought remedy —a true bowel corrective.

AGAROL Brand Compound, the *original* Mineral Oil—Agar-Agar Emulsion, has these special advantages:

Perfect emulsification; stability: pleasant taste without artificial flavouring.

Freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage.

No griping or pain; no nausea or gastric disturbances; not habit forming.

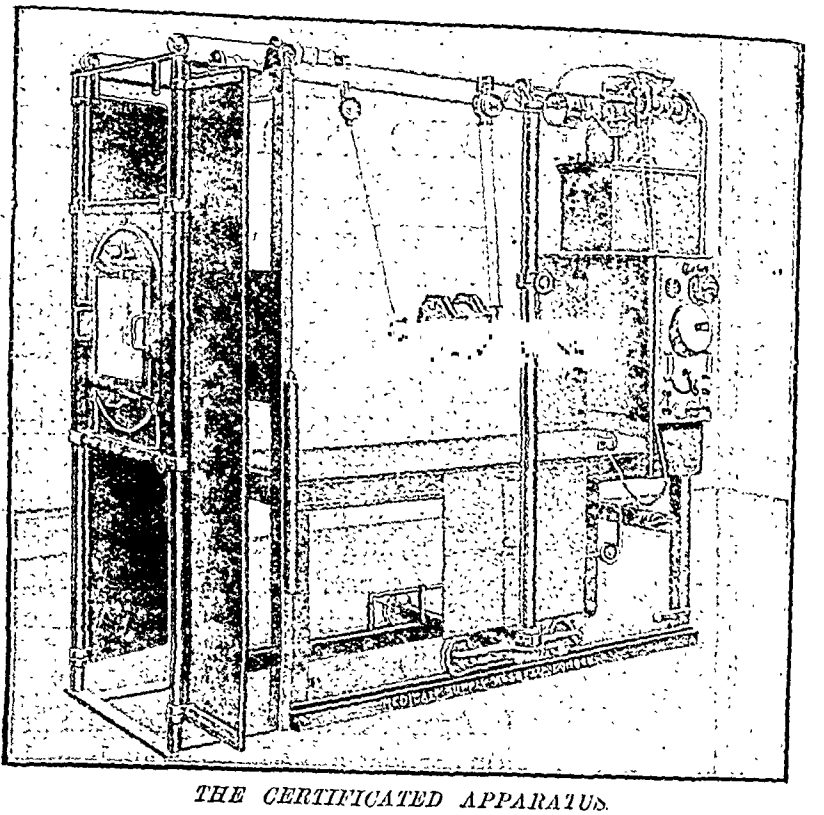
N.P.L.



THE CERTIFICATED APPARATUS.

UNIVERSAL X-RAY APPARATUS

"You switch on—we do the rest!"

This apparatus is exactly what its name implies—a universal X-ray Apparatus. It provides for radiography (general, dental, compression); radiotherapy; horizontal screening; vertical screening. It is the ideal all-round X-ray equipment for hospital, clinic, or private practice.

The UNIQUE TECHNIQUE DIRECTOR has revolutionised radiography. By the turning of a knob, it gives automatically every factor required for producing successful radiograms with certainty. These factors obtained, the setting of the controls is the essence of simplicity.

The N.P.L. APPARATUS GIVES FULL PROTECTION. It is unconditionally certificated by the National Physical Laboratory as complying with the recommendations of the X-ray and Radium Protection Committee.

The N.P.L. Universal X-Ray Apparatus is extremely compact. It occupies a floor space of only 7 ft. 6 in. × 2 ft. 8 in.

Price, complete with all Accessories for Alternating Current - £300

Direct Current - - £345

SALTAIR SURGICAL SERVICE

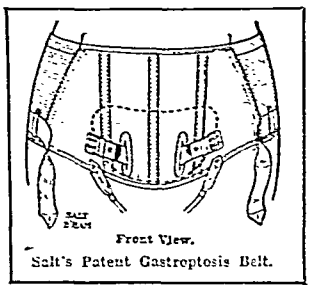
Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

SPECIALIZATION

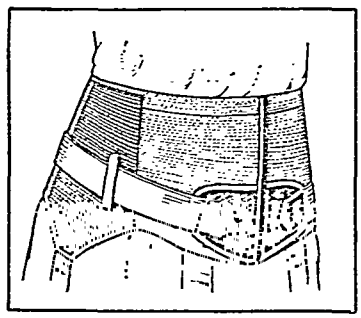
So strong is our belief that one standard appliance cannot possibly be efficient in every form of abdominal weakness that we are continuing to evolve new designs. Our latest catalogue of Belts and Corsets contains no fewer than 27 different styles, each with its own peculiar advantages.



Front View.
Salt's Patent Gastroptosis Belt.

Our patent Gastroptosis Belt is so constructed that the specially shaped sponge rubber pad fits snugly between the anterior superior spines and gives the correct support even when worn by a very thin patient.

Our Ladies' Enteroptosis Belt (Fig. 13) gives good support to the lower abdomen with proper uplift and does not need perineal straps.



A special Belt for every form of abdominal weakness and made only to individual measurements is the only satisfactory method.

ULTRA-VIOLET RAY GLASS PROBLEMS—

TWO VITAL QUESTIONS!

1. *What is the percentage of energy transmission in the curative sector of the spectrum 2950—3200 a.u.?*

OUR ANSWER.

The higher the percentage transmission the greater the efficacy of the ultra-violet ray glass. Sanalux standard thickness 18-20 ozs., has a transmission of 70 per cent. Claims made that any glass can transmit 100 per cent. curative rays cannot be justified owing to such factors as reflection, refraction, and absorption.

2. *Is there any deterioration in effectual transmission of ultra-violet ray glass?*

OUR ANSWER.

Yes, there is bound to be deterioration in all such glasses from the time of manufacture. In SANALUX the maximum deterioration under a temperature of 302° F. is 8 per cent., leaving a static transmission of 65 per cent. after which there is *no further deterioration.*

The above figures are based on a National Physical Laboratory curve. The figures given are the most conservative, since others from independent authorities show an even greater percentage transmission.

Basing our claim on the above, we maintain that, for the substance 18-20 ozs., Sanalux Light o'Health Glass Transmits more curative ultra-violet rays than any other at present on the market.

BEFORE YOU BUY ULTRA-VIOLET RAY GLASS ASK FOR FACTS AND FIGURES AND COMPARE THEM WITH THE CLAIMS FOR

SANALUX *"Light o' Health"* GLASS

Vapo-Cresolene Est. 1879

Sold by all Chemists

Write for descriptive Booklet No. 67B.

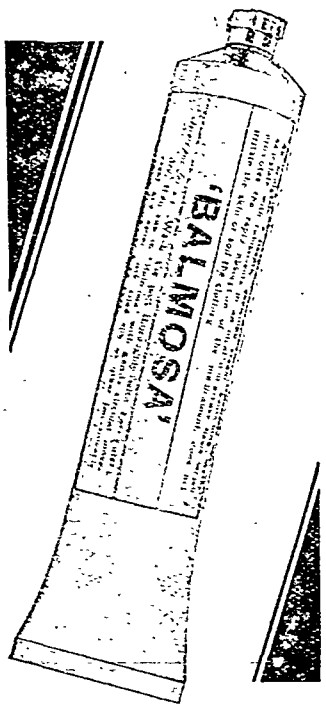
ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

A HIGHLY PENETRATIVE CREAM FOR LOCAL TREATMENT OF RHEUMATISM



Local pain and swelling due to acute rheumatism or joint diseases have proved unusually susceptible to the salicylate present in "Balmosa". The exceptional penetrative properties of the non-greasy base of this cream ensure almost instantaneous action upon the affected part. Pain is speedily relieved; swelling is materially, if not wholly, reduced.

WRIGHT'S LYSOL

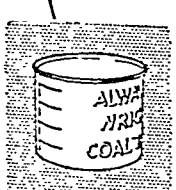
BRITISH MADE :: :: BRITISH OWNED

"LYSOL"—Your patients must always qualify the word.

To ask merely for "Lysol" is dangerous, for they may be given an inferior Lysol that will actually do far more harm than good. Tell them, for their own safety, to insist on Wright's Lysol. It gives sure results—always. It is perfectly pure, non-caustic, and causes no irritation. British owned and made under the strict Rideal-Walker control test by the makers of the world-renowned Wright's Coal Tar Soap—

Producers of Disinfectants for over sixty years.

Tell your patients to say "Wright's" before saying "Lysol." That way lies certain safety and protection.



A handy graduated measure is provided with every bottle.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., C.B.E.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 350 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (*Telephone*: No. 56 Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Mapperley Hill and from its singularly healthy position and comfortable every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

June 16th, 1925.

By Order of the Council of the British Medical Association.
ALFRED COX, Medical Secretary.

Royal Sussex County Hospital, BRIGHTON.

Notice is hereby given that a Meeting of the Elective Committee will be held in the Board Room at the Hospital, on Wednesday, February 6th, at 12.15 p.m., for the purpose of electing an HONORARY MEDICAL CLINICAL ASSISTANT, and such Elective Committee is hereby convened accordingly.

Applications are invited for this office from gentlemen who are Fellows or Members of the Royal College of Physicians of London, Edinburgh, or Dublin, or Graduates in Medicine of one of the Universities of the British Empire, and who are duly registered under the Medical Acts.

Applications, with proof of the necessary qualifications, must reach the Secretary-Supt. at the Hospital before 12 noon on Jan. 28th.

By Order of the Board of Management,
L. L. W. LANCASTER-GAYE,
Secretary-Supt.

The Royal Portsmouth Hospital, PORTSMOUTH.

(Four Resident Medical Officers.)

CASUALTY OFFICER (male, qualified) required to commence on February 1st. Salary at the rate of £100 per annum, with board, etc. Six months' appointment. Eligible on completion of term for appointment as House Surgeon.

Application, stating age, nationality, etc., and copies of three recent testimonials, to be sent to the undersigned on or before January 22nd, from whom all particulars can be obtained.

B. WAGSTAFF, Secretary.

Royal Sussex County Hospital, BRIGHTON. (225 Beds.)

HOUSE SURGEON (male) required about the end of January, with charge of beds, part casualties and anæsthetics. Salary £150 per annum, with board, residence, and laundry. Candidates must hold Medical and Surgical qualifications of the British Empire, and be duly registered under the Medical Acts. They must be unmarried and, when elected, under 30 years of age. Applications, with copies of testimonials, should be sent to the undersigned immediately.

L. L. W. LANCASTER-GAYE,
Secretary-Supt.

City Mental Hospital, NOTTINGHAM.

Wanted, JUNIOR ASSISTANT MEDICAL OFFICER (male), preferably with some Post-Graduate General Hospital experience. Salary £350 to £400 per annum, by two £25 increases, all found, with an additional £50 per annum on obtaining the D.P.M. Application, with fullest particulars and names of two referees, should be sent to the Medical Superintendent of the above-named Hospital.

General Infirmary, Salisbury. (General Hospital—151 Beds.)

A RESIDENT MEDICAL OFFICER (male) required. Candidates must be unmarried, fully qualified, and registered. Salary £150, with board, etc. Applications, with copies of testimonials, to be sent to the House Governor and Secretary at once.

Cardiff City Mental Hospital, WHITCHURCH, Near CARDIFF.

OFFICE OF MEDICAL SUPERINTENDENT.

The Committee of Visitors invite applications for the above. Commencing salary £1,000 a year, with unfurnished house, rates, taxes, water supply, light, fuel, vegetables, and laundry free. Candidates, who must be of the male sex, must not exceed 40 years of age, must be duly qualified and registered under the Medical Acts, must be actually engaged in Mental Hospital practice, and hold a Diploma in Psychological Medicine. The appointment is subject to the conditions of the Asylums Officers Superannuation Act, 1909, and to all Rules and Regulations of the Mental Hospital, and any others which may hereafter be made. Three months' notice of termination of appointment on either side. Forms of application, with full details, to be obtained from the Town Clerk, City Hall, Cardiff. Canvassing, directly or indirectly, any member of the Committee will be a disqualification. The successful candidate will be required satisfactorily to pass a medical examination.

The Elizabeth Garrett Anderson HOSPITAL, Euston Road.

Wanted, fully qualified medical woman as ASSISTANT PATHOLOGIST (full-time). Particulars of post can be obtained from the Secretary, to whom applications, with testimonials, should be sent before February 1st next.

IMOGEN H. MURPHY, Secretary.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in January, 1929. Applications should reach the War Office not later than January 25th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of January. They must be under 28 years of age on February 1st, 1929, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Officers serve on an average 3 to 4 years at home to 5 years abroad.

Pay and Allowances—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on retirement.—After 7 years' service £1,000.
" 15 " " £2,800.
" 18 " " £3,500.

Current rates of retired pay range from £372 per annum normally earned by a Major after 20 years' service to £940 per annum, the maximum for which a Major-General is eligible.

The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Allowance.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

All particulars may be obtained by application, in writing or personally, to The Under Secretary of State, The War Office (A.M.D.1), Whitehall, London, S.W.1.

Malayan Medical Service.

APPOINTMENTS.

VACANCIES exist at present for MEDICAL OFFICERS in the MALAYAN MEDICAL SERVICE. Candidates, who should be British subjects of European parentage and not over 35 years of age, should apply to the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, for the necessary form of application. Preference is given to candidates who have held Hospital appointments as House Surgeons and House Physicians. Selected candidates are required to attend one of the Schools of Tropical Medicine, the fees for their tuition being defrayed by Government, and an allowance paid during their instruction.

Salaries.

2. The initial salary of a Medical Officer is $500 per mensem (£700 per annum), rising by annual increments of $25 per mensem (£35 per annum) to $550 per mensem (£770 per annum). Officers are appointed on probation for a period of three years and then become eligible for confirmation, after which the salary rises by annual increments of $25 per mensem (£35 per annum) to $800 per mensem (£1,120 per annum).

Allowances.

3. In addition to salary, there is at present a temporary allowance of 10 per cent. of salary to unmarried officers and 20 per cent. to married officers. A non-pensionable allowance of $100 per mensem (£140 per annum) is paid to officers holding the Diploma in Public Health.

Currency.

4. The Straits dollar is equivalent to 2s. 4d. of English currency. The rate is liable to alteration, but has remained unchanged for many years past, and so far as can be foreseen no change is anticipated.

Passages.

5. Free first-class passages are provided on first appointment and on leave.

Quarters.

6. Quarters are usually available and are provided at a rental which in no case exceeds 6 per cent. of the officer's salary.

Private Practice.

7. Private practice is not allowed, but consultation with another practitioner is permitted.

Thakeham Union.

MEDICAL OFFICER & PUBLIC VACCINATOR.

The Guardians invite applications from fully qualified medical practitioners for the appointment of Medical Officer and Public Vaccinator of the No. 1 District (9 Parishes with an estimated population of 4,050).

The salary as Medical Officer will be at the rate of £112 per annum, and the fees paid in respect of vaccinations are 8/- for each successful case, the appointment of Public Vaccinator being subject to one month's notice on either side.

The appointment (other than that of Public Vaccinator) will be subject to the Provisions of the Poor Law Officers Superannuation Act.

The person appointed will be required to attend at the houses of the outdoor patients, to supply all drugs, medicine, and appliances free (other than anæsthetics and cod-liver oil), and generally conform with the Orders of the Ministry of Health and the Guardians.

Applications, in candidates' own handwriting, stating age, qualifications, and present and previous occupations, and accompanied by copies of recent testimonials, must reach my office not later than Wednesday, January 30th instant.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Storrington, Pulborough, Sussex. January 14th, 1929

PERCY AYLING, Clerk to the Guardians.

West London Hospital,

Hammersmith Road, W.6. (226 Beds.)

Applications are invited for the post of HONORARY OBSTETRIC REGISTRAR for a period of one year. The holder of the post is eligible for re-election annually for a total period of not more than three years. The duties include the preparation of the Obstetric Registrar's Report for the year, and the supervision of the records of cases. The candidate appointed must be available as a substitute for the Surgeon and Assistant Surgeon for Diseases of Women, and for emergency operations when required, and be prepared to undertake such teaching for the Post-Graduate College as the Board may approve.

Candidates are required to be registered under the Medical Act; to send applications to reach me not later than Monday, February 18th; to attend the Medical Council Meeting on Friday, February 22nd at 4.30 p.m., and prior to that date to call upon and send copies of application and testimonials to each Member thereof; to abstain from canvassing, but nevertheless to send copies of application and testimonials to each Member of the Board of Management, at whose Meeting on Tuesday, February 26th, at 5 p.m., candidates must be in attendance.

H. A. MADGE, Secretary.

Borough of Leyton.

ASSISTANT MEDICAL OFFICER (Female).

Applications are invited for the appointment of Assistant Medical Officer.

Age not to exceed 45.

The inclusive salary will be at the rate of £600 per annum.

The duties will be principally in connection with maternity and child welfare and school medical services.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the approval of the Minister of Health.

Applications must be made on prescribed forms, which can be obtained by sending a stamped, addressed envelope to the undersigned.

Applications, endorsed "Assistant Medical Officer," accompanied by copies of not more than three testimonials of recent date, must reach me not later than the 31st instant.

Canvassing, directly or indirectly, will be a disqualification.

Town Hall, Leyton, E.10. January 18th, 1929

JNO. ATKINSON, Town Clerk.

Torbay Hospital, Torquay.

(AMENDED ADVERTISEMENT)

Metropolitan Asylums Board.

BIO-CHEMIST AT THE BOARD'S ANTITOXIN ESTABLISHMENT.

The Board invite applications for the appointment of BIO-CHEMIST at their Antitoxin Establishment. The Laboratories and Stables are at Sutton, Surrey.

The candidate appointed will be required to assist generally in the work of the laboratories, especially with the chemical side of the work, such as the concentration of toxin and anti-toxin, preparation of media, etc.; to make himself acquainted with the general running of the laboratories, and so be in a position to take charge, if required; and to conduct researches bearing especially on bio-chemical problems, subject to the approval of the Director.

Evidence of previous research work in bio-chemistry is desirable, and, although it is not essential that the candidate appointed should already be equipped with a special experience of bacteriology and serology, he will be expected to acquire knowledge of the current laboratory work on these subjects, with a view to the co-ordination of bacteriological and bio-chemical interests.

The commencing salary is at the rate of £600 per annum.

Application form containing full particulars of the appointment may be obtained by forwarding stamped addressed foolscap envelope to the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4, to whom completed applications must be returned not later than 10 a.m. on Wednesday, February 6th.

ALLAN POWELL, Clerk to the Board.

St. Bartholomew's Hospital,

ROCHESTER, KENT.
(126 Beds.)
Rochester, Chatham, Gillingham, and District.

The House and Finance Committee invite applications for the post of HOUSE PHYSICIAN, vacant March 1st.

Candidates must be unmarried, qualified, and registered medical men. The appointment is for six months. Salary is at the rate of £175 per annum, with board, residence, and laundry.

The officer appointed will have charge of the Medical beds. Some knowledge of Ophthalmic work is desirable.

Applications, stating age, qualification, and experience, accompanied by copies of three recent testimonials, to be sent to the Secretary not later than Thursday, January 31st.

C. SPEYER,
January 11th, 1929. Secretary.

Royal Berkshire Hospital,

READING.

The Board of Management invite applications for the appointment of an HONORARY ASSISTANT ANÆSTHETIST.

Candidates must be fully qualified and registered.

The elected candidate will be appointed for the period ending on the first Tuesday in March, 1930, and will be eligible for re-election.

Canvassing by, or on behalf of, a candidate will disqualify him.

Applications, accompanied by not more than three testimonials, should be addressed to the Secretary, and reach him not later than the first post on Saturday, February 2nd.

HERMAN BURNEY,
Reading, January 19th, 1929. Secretary.

Worcester County and City

MENTAL HOSPITAL, POWICK, NEAR WORCESTER.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LONDON, S.W.—RESIDENTIAL SUBURB.—Small PRACTICE, offering scope for increase. Gross cash receipts for immediate past 12 months £706, including panel of 155. Fees 3/6, 5/- upwards. Midwifery 5 guineas. Small compact house, on main road, with 2 reception, 4 bedrooms, etc. Price £1,150, payable £400 down and balance by yearly instalments of £85. Premium for quick sale £1,000, to include drugs, fittings, fixtures, etc.
2. PARTNERSHIP.—The third share of a very old-established mixed-class Practice, in a pleasant London suburb, is for disposal owing to the retirement (through ill health) of the Junior partner. Held 24 years by remaining. Cash receipts average about £2,700 p.a., including appts. producing £340 and panel of 1,000. Visits 3/6 to 21/-. Good house available, with ample accommodation. Rent £85 on lease. Premium 2 years' purchase. Excellent scope.
3. LONDON, SOUTH-WEST.—RESIDENTIAL DISTRICT.—PARTNERSHIP.—A three-tenths share, to commence with, is offered in a rapidly increasing good mixed-class Practice, producing about £2,500 p.a., including panel of over 2,000. Surgery fees 2/- to 3/6, visits 3/6 to 5/-. Suitable corner house, with 2 reception, 6 bedrooms, etc., consulting room, and dispensary. Small garden. Rent on lease £100 p.a. Six months' preliminary assistantship. Scotch Graduate, having Hospital experience, essential.
4. KENT.—GROWING DISTRICT, within 15 miles of London.—PARTNERSHIP.—A one-half share is for disposal in a very sound chiefly better and middle-class Practice, established many years, and held by the remaining partner over 4 years. Gross cash receipts for the past three years £2,528, including panel of 900. No appointments. Fees from 3/- to 21/-. Midwifery 3 to 30 guineas (about 25 cases yearly) Very suitable modern house, with 2 reception, 4 bedrooms, good bathroom, etc. Consulting room. Electric light. Small garden. Garage. Price for freehold about £2,100, nearly all of which could remain on mortgage. Good sport and schools, and excellent social facilities. Premium 2 years' purchase.
5. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 3/6 to 21/-, medicine extra. Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium 1½ years' purchase.
6. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
7. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.
8. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share (to commence with) is for disposal, owing to the retirement of the senior partner, in sound middle-class Practice, situated in rapidly developing district Income for the immediate past year £2,124. Consultations 3/6 to 10/6, visits 4/6 to 21/-. Good freehold house, price £1,500; or would be rented on lease at £90 p.a. Low expenses. Premium 2 years' purchase.
9. OUTLYING WESTERN SUBURB.—Old-established mixed general PRACTICE Income for the immediate past year about £2,500, including panel of between 1,400 and 1,500. Fees 3/6 to 10/6. Midwifery from 3 gns. The district is rapidly developing and there is great scope. Good house, with garden and garage. Price £2,000. Premium £3,500.
10. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appts. worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly. Moderate expenses Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Price for freehold £1,500 Premium £4,500
11. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, producing for the last twelve months about £700, and rapidly increasing. Panel of 150. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery. 2 gns upwards. Good house in excellent repair, with 2 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300 Premium £1,400.
12. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, situated in good hunting centre. Gross cash receipts for past 12 months about £1,000 p.a., including panel of 600. Advice and medicine from 3/6, visits 3/6 upwards, with medicine extra. Lowest midwifery 2½ gns. Exceptionally attractive house, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1½ acres, and 12 acres of grassland. Recently re-decorated throughout. Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
13. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/ to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools Price for practice and house, £3,000.
14. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200. Premium 1½ years' purchase.
15. BORDERS OF NORFOLK AND SUFFOLK.—Old-established middle-class PRACTICE, producing about £1,100 p.a., including panel of over 500. Visits 3/6 upwards. Midwifery from 2 gns., about 30 cases. Modernized old country house, with ample accom. and large garden; e.l.; all in good order. Price for f'hld. £2,500. Prem. £1,500.
16. DERBYSHIRE.—PARTNERSHIP.—A half share in a very sound panel and club practice, producing £3,200 p.a. Panel of over 3,000. Fees 3/6 to 5/-, medicine extra. Expenses small. Modern house, in good order, with pleasant garden. Garage. Price for freehold £1,500, part on mortgage. Premium £3,200, half down and balance by instalments over 4 years.
17. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£80, with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented Prem. 1½ yrs' pur.
18. WILTSHIRE.—Unopposed old-estab. Country PRACTICE, situated in very pretty district and averaging £700 p.a., including Union appt. £70, and panel producing £450. Nearest opposition 3½ miles. Railway station 1 mile. House stands in own grounds of 1½ acres, with tennis court, garage, etc., and contains surgery, 3 reception, 5 or 6 bedrooms, bathroom (h. & c.). Electric light plant installed. Vendor's freehold, price £2,500, all of which could remain on mortgage if wished. Premium £1,050
19. MANCHESTER.—Rapidly developing outlying suburb. Good middle- and working-class PRACTICE, increasing and producing for the last 12 months over £1,500. Panel of 700. Fees from 3/6. Particularly good house, specially built, and containing 3 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price £3,850, part on mortgage. Premium £2,250.
20. ESSEX COAST.—FAVOURITE RESORT.—PARTNERSHIP.—A one-third share to commence with in an old-established middle-class Practice. Average income of about £2,800. Panel of 600. Visits 4/6 to 21/-. Little midwifery. Suitable accommodation can be obtained. Premium 2 years' purchase.
21. BEDFORDSHIRE.—Small Country PRACTICE, at present producing at the rate of £400 p.a., but offering good scope. Fees 3/6 to 10/6, medicine extra. Good house, with 2 reception, 6 bedrooms, etc. Separate entrance to professional rooms. Can be rented on lease. Price for Practice and house £1,050.

'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:—

Ready solubility in water. Well tolerated. Absence of local reaction on injection.

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Physicians are invited to write for further particulars and clinical trial samples.

CASSELL AND COMPANY, LTD.

SEVENTH EDITION. NOW READY.

ELEMENTS OF SURGICAL DIAGNOSIS

By Sir ALFRED PEARCE GOULD.

Revised by ERIC PEARCE GOULD, M.D., M.Ch.Oxon., F.R.C.S.Eng.

This Manual has been subjected to a careful revision and is now once more abreast of the knowledge upon which the diagnosis of surgical conditions is based.

The increasing rôle played by X-rays in surgical diagnosis is signalized by the addition of several new radiographic plates and appropriate recognition in the text. Cholecystography, and the use of Lipiodol with X-rays, have been introduced into the new edition.

Foolscap 8vo. 714 pages. With 26 Radiographic Plates. **12s. 6d.** net.

NEW WORK.

THE ESSENTIALS OF MEDICAL DIAGNOSIS

A Manual for Students and Practitioners

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D., F.R.C.P.Lond.,
and A. E. GOW, M.D., F.R.C.P.Lond.

This Manual consists of concise descriptions of the methods of investigating cases of disease in the manner actually carried out in practice. The authors' plan is to work from the patient and his complaint to the disease from which he suffers, and not in the opposite direction.

"*Well written and thoroughly practical.*"—BRITISH MEDICAL JOURNAL.

"*A successful attempt . . . to relay the foundation-stones of the art of diagnosis.*"—LANCET.

Crown 8vo. 702 pages. With 8 Colour and 11 Black-and-White Plates, and Figures and Charts in the Text. **16s.** net.

NINTH EDITION. READY FEB. 7th.

MANSON'S TROPICAL DISEASES

Edited by PHILIP H. MANSON-BAHR,

D.S.O., M.A., M.D., D.T.M. & H.Cantab., F.R.C.P.Lond.

The Ninth Edition of this Manual brings together the new knowledge acquired by various workers in the field of tropical medicine. A notable feature is the extension and amplification of methods of treatment which are becoming more and more stabilized. Every chapter has been drastically revised, and many parts of the book have been rewritten.

The sections devoted to protozoology and laboratory technique have also been thoroughly revised, and the illustrations have been reinforced by the addition of nine new plates and some thirty new text-figures.

Demy 8vo. 942 pages. With 23 Colour and 12 Half-Tone Plates, 401 Illustrations in the Text, 6 Maps and 34 Charts. **31s. 6d.** net.

NEW WORK. READY FEB. 7th.

TROPICAL NURSING

By A. L. GREGG, M.A., M.D., M.Ch., D.T.M. & H.Lond.

With a Foreword by the Hon. Sir ARTHUR STANLEY, G.B.E., C.B., M.V.O.

TROPICAL NURSING has been written to meet the requirements of nurses working in the tropics.

The nursing of the principal tropical diseases is lucidly dealt with, and there is also much practical advice on personal hygiene, food, drink, clothes and kit, etc. Other sections are devoted to nursing technique and the care of the eyes.

Foolscap 8vo. 212 pages. With Illustration in the Text. **6s.** net.

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4.

J. & A. CHURCHILL

85th Annual Issue. 2,200 pages. 54,000 names. 14 Pictures of Spas. 36s. net, postage 1s.

London: 40, Gloucester Place, Portman Square, W.1

THE PRINCIPLES OF CLINICAL PATHOLOGY IN PRACTICE.

A guide to the Interpretation of Laboratory Investigations for the use of those engaged in the Practice of Medicine.

By GEOFFREY BOURNE, M.D.(Lond.), M.R.C.P., and KENNETH STONE, M.D.(Oxon.), M.R.C.P.

This original work does not profess to deal with the minutiae of laboratory technique. It makes its appeal to the clinician, whose interest inclines naturally towards the application of pathology in his own practice. In a word, the book deals with the value of results obtained, *not with the methods of obtaining them. It is in this respect unique.*

Contents include: Specific Infections—Diseases of the Blood—Diseases of the Cardiovascular System—Diseases of the Gastro-Intestinal System—Diseases of the Respiratory System—Diseases of the Urogenital System—Metabolic Diseases—Allergic Diseases—Collection of Pathological Material.

Pp. 592 + x. 10 Illustrations. 16s. net.

OXFORD UNIVERSITY PRESS Humphrey Milford Amen House, London, E.C.4.

LEWIS'S PUBLICATIONS.

With 25 Illustrations, including 17 Plates. 9s. net; postage 5d.

STERILITY IN WOMEN: Diagnosis and Treatment.

By SIDNEY FORSDIKE, M.D., B.S.Lond., F.R.C.S.Eng. & Edin., Surgeon to the Hospital for Women, Soho Square, London; Gynæcological *Surgeon to the Kensington, Fulham, and Chelsea Hospital; Author of* "The Effects of Radium upon Living Tissues," etc.

"*The monograph shows in every page evidence of rich personal experience, and will well repay the most careful study.*"—THE LANCET.

With 72 Illustrations, including 8 plates. Demy 8vo. 9s. net; postage 6d.

HERNIA AND HERNIOPLASTY.

By ERNEST M. COWELL, D.S.O., M.D., B.S.Lond., F.R.C.S.Eng., Surgeon, Croydon Gen. Hosp.; Hunterian Prof., Roy. Coll. of Surg. of Eng., etc. With an introduction by Sir ARTHUR KEITH, F.R.C.S.

"*The clinical side is fully dealt with . . . a valuable study.*"
—BRITISH MEDICAL JOURNAL.

London: H. K. LEWIS & Co. Ltd., 136, Gower St. & 24, Gower Place, W.C.1.

That book you want!

Foyles can supply it. Special Department for Books on Medicine, Surgery, Nursing, and allied subjects. Over 1,250,000 of the best books—New, Secondhand Out-of-Print—on all subjects in stock. Twenty-five Departments. If unable to call and look over the stock at leisure, send for Catalogue, outlining requirements and interests. Books sent on approval to any part of the world. Deferred Payments arranged (in Great Britain) for all books.

Books you no longer want!
Foyles will buy them—a single volume up to a library.

SURGICAL PATHOLOGY

By **CECIL P. G. WAKELEY**, F.R.C.S.(Eng.), F.R.S.(Edin.),
Hunterian Professor, Royal College of Surgeons of England: Surgeon, King's College Hospital;

And **ST. J. D. BUXTON**, M.B., B.S.(Lond.), F.R.C.S.(Eng.),
Surgeon and Orthopædic Surgeon, King's College Hospital.

WITH 392 ILLUSTRATIONS (50 FULLY COLOURED).

In preparing this volume on 'Surgical Pathology' the aim has been to put forward such an account of the pathological side of surgery as may help readers with their clinical work. An endeavour has been made to trace the pathology of each surgical disease from its inception, and to illustrate the conditions as far as possible.

Satisfactory representations of many subjects of surgical pathology are obtained only with extreme difficulty; consistent endeavour has therefore been made to select the best illustrations available in each case whether original or not. The majority are new and have been made from actual specimens. X-Ray photographs are also included, since they often show the pathological conditions of bones to the best advantage, and they should assist the student in forming a clear mental picture of these conditions.

Bristol: JOHN WRIGHT & SONS Ltd. London: SIMPKIN MARSHALL Ltd

From EDWARD ARNOLD & CO.'s List

NEW SECOND EDITION READY JAN. 31st. REVISED AND ENLARGED.

A Text-Book of Pathology

By ROBERT MUIR, M.A., M.D., Sc.D., LL.D., F.R.S.,
Professor of Pathology, University of Glasgow; Pathologist to the Western Infirmary, Glasgow.

The New Edition, enlarged by about 100 pages and 60 illustrations, will contain viii + 872 pages, with 501 illustrations. Price as before, 35s. net.

The Lancet (of first edition).—"Prof. Muir has written a book which will, we predict, have an immediate success. The general practitioner who desires to keep abreast of modern pathological teaching cannot do better than turn to it, while the student will find it not only a safe guide to success in examinations, but a stimulating presentation of a subject upon which his final studies must be founded."

Chemo-therapeutic Treatment of Gonorrhœa with

CONTRAMINE

Contramine is a complex organic sulphur compound which has proved to be of remarkable value in the treatment of the chronic complications of gonorrhœa.

Clinical evidence shows that the benefits resulting from intramuscular injections of Contramine are mainly due to the fact that it definitely provides the patient with the power to resist the attacks of disease germs.

Contramine also possesses the power to soften fibrous tissue, a property which is utilised in the dilation of strictures. Three intramuscular injections at weekly intervals will enable most undilatable strictures to be dilated.

In spite of its great therapeutic potency Contramine is non-toxic and it induces no pain either during or following injection.

Although Contramine is recommended specially in the treatment of gonorrhœa it is also of great use in rheumatism, arthritis, and fibrositis, even when not caused by the gonococcus.

Contramine is issued in solution in ampoules of 1 c.c. and 2 c.c. and in the form of pessaries for the treatment of gonorrhœa in women.

Rational Alkaline Medication

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

must be adapted to the physiological requirements of the human organism, in order to neutralize excess acid products and restore alkaline balance, without the risk of intoxication.
A trial will promptly convince you of the value of Alka-Zane as antacid, diuretic, and to restore normal alkalinity, in gouty and rheumatic conditions, gastric or intestinal hyperacidity, and in certain skin diseases.

ALKA-ZANE

Therapeusis in Pulmonary Tuberculosis

By increasing the calcium content of the blood the resistance of the whole organism against the bacterial toxins is greatly strengthened, there is a decrease in the excitability of the nerves, and a definite improvement in the functions of the alimentary canal, due to the combined anti-toxic and astringent effect of the calcium salts.

Successful calcium therapy depends upon calcium retention. The calcium-sodium-lactate compound, presented as a double salt in the form of Kalzana is easily absorbed and well retained. The sodium-lactate is changed within the body to sodium-carbonate, which raises the blood alkalinity to the extent necessary to secure calcium retention.

"The Practitioner," June, 1924, says:
"It is indicated in all conditions in which a lime food is required, particularly because Kalzana promotes calcium retention."

Kalzana is in daily use at over 200 British Sanatoria and Hospitals.

Supplied in air-tight packets at 2/9 & 4/11

Kalzana

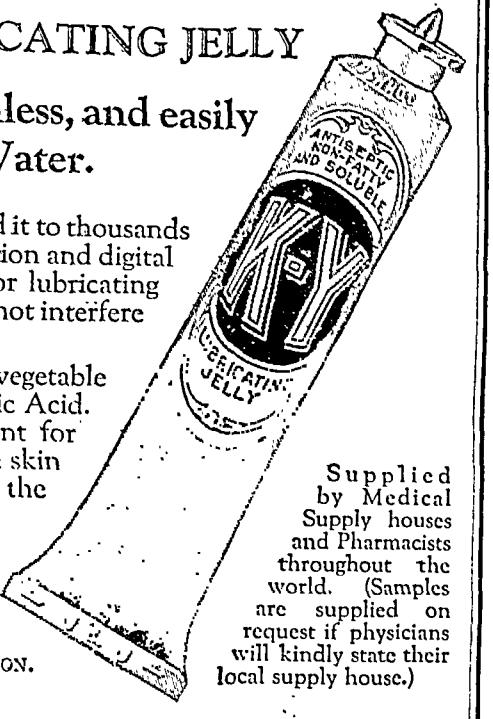
"K-Y" LUBRICATING JELLY

Non-greasy, Stainless, and easily removed with Water.

The distinctive properties of "K-Y" have commended it to thousands of physicians and surgeons for instrument introduction and digital examination. In Electrotherapy "K-Y" is useful for lubricating glass and metal electrodes. Being non-greasy it does not interfere with the current.

"K-Y" is a skilfully blended compound of certain vegetable products and correctly balanced proportions of Boric Acid. Its soothing and healing properties make it excellent for burns, chafing, and all cases where protection of the skin is rendered necessary. It does not interfere with the application of local remedies.

"K-Y" is enclosed and protected from the air by a convenient compressible tube. It never spoils or becomes rancid and odorous.



Supplied by Medical Supply houses and Pharmacists throughout the world. (Samples are supplied on request if physicians will kindly state their local supply house.)

Manufactured by

Johnson & Johnson (GT. BRITAIN) LTD., SLOUGH AND LONDON.

The Doctor orders Thermogene because:

(1) He knows it to be cleanly in use; whereas poultices and liniments soil clothes and skin, thus making examination with hand or stethoscope both unpleasant and difficult.

(2) He knows it to be fool-proof. It is always ready, and calls for no skill in preparation or application. It is never too hot, and cannot get cold and clammy. Scalding and chilling are alike impossible.

(3) He knows that, in addition to—or because of—its definite therapeutic action in promoting surface circulation and in stimulating healthy metabolism it invariably comforts and soothes the patient, and eases his pain.

THERMOGENE

MEDICATED WADDING

is carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

A full-size box of "Thermogene" with an interesting booklet on "Surface Therapy" will be sent free to any medical man who is unfamiliar with "Thermogene" and its many uses in practice. The Thermogene Co., Ltd., Queen's Rd., Hayward's Heath, Sussex

'PANOPEPTON'

THE FOOD FOR THE SICK

Supplies directly available energising food; especially designed to make no draft upon the strength of the enfeebled organism.

'PANOPEPTON' contains, in stable agreeable solution, 24% of solids, derived by physiological hydrolysis from prime lean beef and whole wheat, in a scientifically balanced ratio.

'PANOPEPTON' has nourished and restored in many cases where the patient has steadily lost strength on other foods.

SUPPLIED IN 12-oz. BOTTLES.

'ENZYMOL'

A SURGICAL SOLVENT AND ANTISEPTIC

AN EXTRACT OF THE GASTRIC GLAND OBTAINED BY DIRECT SOLUTION, ESPECIALLY PREPARED FOR EXTERNAL APPLICATION.

'ENZYMOL' exerts remarkable solvent, healing, antiseptic, and deodorizing action in the treatment of pus cases in general, gangrene, abscesses, sinuses, leg ulcers, etc. etc.

SUPPLIED IN 4-oz. BOTTLES.

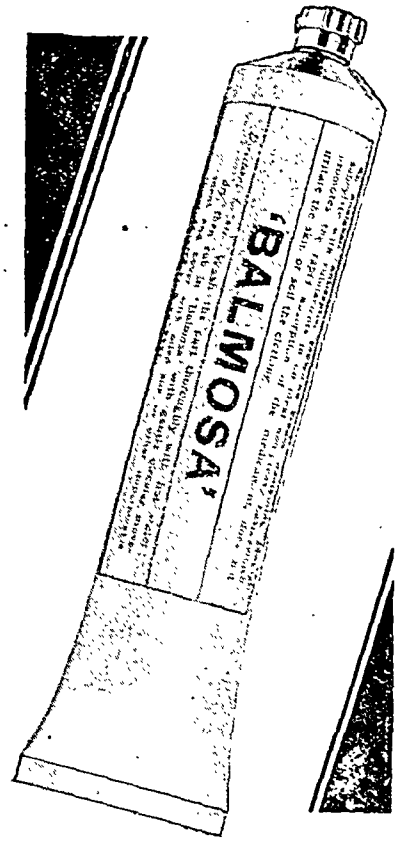
A HIGHLY PENETRATIVE CREAM FOR LOCAL TREATMENT OF RHEUMATISM



Local pain and swelling due to acute rheumatism or joint diseases have proved unusually susceptible to the salicylate present in "Balmosa". The exceptional penetrative properties of the non-greasy base of this cream ensure almost-instantaneous action upon the affected part. Pain is speedily relieved; swelling is materially, if not wholly, reduced.

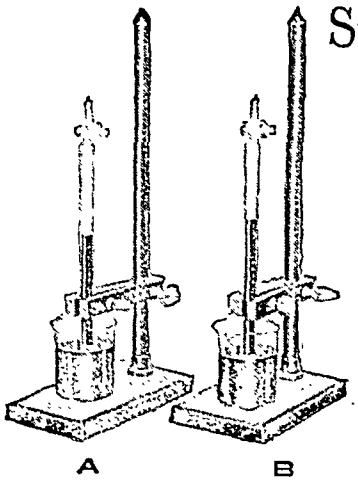
Dioxogen

(Trade H_2O_2 12V Mark)

means

Stable Hydrogen Peroxide



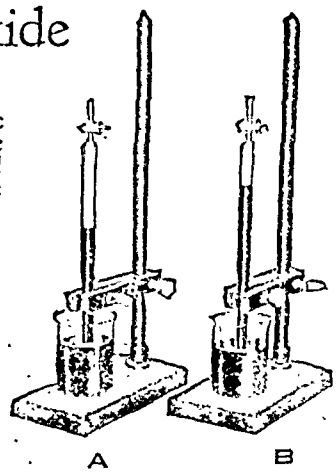
Showing volumes of Oxygen liberated by (A) "Dioxogen," and (B) the same quantity of a fresh sample of ordinary Hydrogen Peroxide (10 volumes).

The merits of nascent oxygen as an antiseptic are too well known to require reiteration. The difficulty lies in obtaining a convenient and reliable source and, while Hydrogen Peroxide is most convenient in use, the unreliability, both in strength and in keeping properties, of the ordinary commercial product seriously limits its utility in practice.

"DIOXOGEN" definitely overcomes this disadvantage. Its stability is remarkable. It can be boiled or frozen without impairment of therapeutic power and, even after being kept for long periods, will yield its full volume of oxygen. This dependability of "Dioxogen" is well exemplified in the accompanying illustrations.

Descriptive literature and a clinical trial sample will be sent post free on application.

Sole Distributors:



Showing volumes of Oxygen liberated by the same quantity of (A) "Dioxogen" and (B) Hydrogen Peroxide (10 volumes), both having been kept for the same period.

OVALTINE

MILK AND ITS DEFICIENCIES.

In the dietary of fevers and infectious diseases milk probably holds the most important position for one reason, that it leaves a residue which is not mechanically irritating.

Milk, however, has certain objections. It is deficient in carbohydrate; it is also repugnant to many people and rapidly becomes tiresome to others.

"Ovaltine" improves milk as a nutritional agent wonderfully. It relieves the monotony of a milk diet. Further, the addition of "Ovaltine" to milk not only makes it more attractive to the taste, but raises the nutritive power and renders the milk twice as digestible—valuable features where dyspepsia is associated with constitutional disturbance.

"Ovaltine" adjusts the carbohydrate deficiency in cow's milk and converts the curd into a light, flaky, easily digested coagulum. It also provides nutriment of inestimable value for maintaining adequate nutrition

A liberal trial supply will be sent to members of the medical profession in private or hospital practice.

INFLUENZA

AS the nose and throat in this disease are the only routes of infection, it follows that the organism should be easily destroyed or attenuated by an insufflation powder of high bactericidal value. This is now readily available in the form of Dimol Snuff.

This Snuff is guaranteed to be equal in bactericidal value to 20 per cent. pure carbolic acid and to be perfectly free from all deleterious action on the mucosa. As a prophylactic measure the use of this powerful non-toxic powder is clearly indicated.

Common Colds, Nasal Catarrh, etc.

A nose and throat specialist of 30 years' experience, who has been prescribing Dimol Snuff for over three years in the disinfection of the nares and nasopharynx, writes:

"The discomforts of nasal catarrh are known to everybody, especially in the fluctuating temperatures of an English winter; but there is no reason why any type of this common ailment should not be dealt with promptly and (1) aborted in its incipient stages, (2) ameliorated in its active stages, and (3) quickly cured, with the aid of Dimol Snuff. . . ."

"This Snuff, taken three or four times a day during an epidemic of influenza, should be a perfect and pleasant preventive to the insidious settlement of the pervading bacillus in the nose and throat."

Samples and Literature will be sent on application to the

DIMOL LABORATORIES LIMITED, 40, Ludgate Hill, London, E.C.4.

Absorbs Intestinal Toxins

Over thirty-six separate poisons have been found in the intestinal tract in cases of alimentary toxemia. These consist of bile acids and alkaline wastes secreted by the intestinal mucous membrane, in addition to a variety of bacterial ptomaines and toxins.

Nujol is a highly active solvent. If it be shaken with a watery solution of indol, more than half the indol is quickly taken up. Nujol readily dissolves these waste and poisonous substances, many of which are more soluble in liquid petrolatum than in water.

Thus Nujol, which is not absorbable, takes up a very considerable portion of toxins found present in the intestinal tract and prevents their absorption into the body. The brownish colour of Nujol as seen in the stool is due to the substances which it holds in solution.

Laxatives which liquefy the intestinal contents and provoke anti-peristalsis, frequently increase the absorption of intestinal toxins. Nujol not only dissolves and removes intestinal toxins, some of which are highly active poisons even in minute quantities, but also by speeding up the intestinal rate of flow it prevents their formation. Effective in all types of constipation.

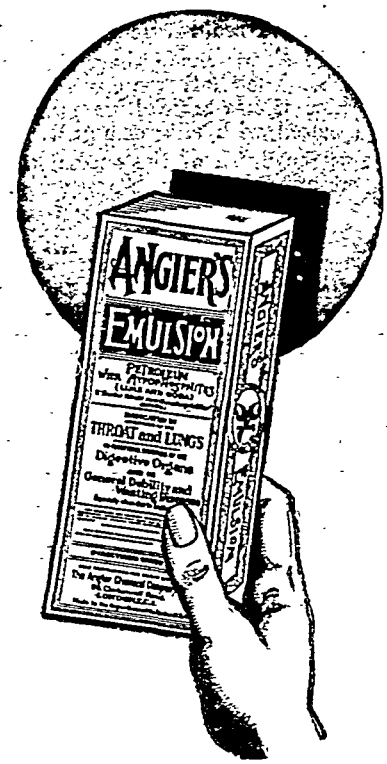
In Convalescence

after Influenza, Pleurisy, Pneumonia, Bronchitis.



The soothing, inflammation-allaying properties of Angier's Emulsion and its general tonic effects especially commend its use in convalescence from acute respiratory affections. It will clear up any remaining catarrh, whether of the respiratory or digestive organs. It will restore tone to the digestive functions, and greatly improve assimilation and nutrition.

An absolutely perfect emulsion, it is presented in a form pleasing to the taste, and acceptable to the most fastidious. Moreover, it can be administered to advantage in conjunction with other remedies, such as salol, aspirin, bismuth, etc.

Angier's Emulsion is made with petroleum specially purified for internal use. It is the original petroleum emulsion — the result of many years of careful research and experiment.

Local Anæsthesia in Surgical Practice

OPERATION ON BRAIN.

Typical Case.

A. B., aged 42 years.

Diagnosis: Advanced optic neuritis.

Anæsthesia: 60 c.c. of a 0.7 per cent. Novocain-Adrenaline solution.

Operation: A transverse infiltration block was made above the external ear, with a vertical line along the proposed line of incision. The skull was opened over an area of 5 by 7 cm. The dura was opened after the ligation of two arterial branches. The opening was covered by the temporal muscle and the skin closed with silkworm gut.

NOTE.—The patient remarked at the finish of the operation that, if this was all there is to such an operation, he would not mind having one every day.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

Full technique of this and one hundred other operations under local anæsthesia will be found in the above work published by Henry Kimpton, 265, High Holborn, London, W.C.1.

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

PLURIGLANDULAR DISPENSING

The choice of pluriglandular formulæ for the various conditions in which organo-therapy is indicated is often difficult. There may be a considerable difference of opinion as to dosage, and physicians may from their practical experience decide something quite definite but which is probably not in accordance with the usual formulæ.

The growing and varied needs of the profession in this respect are well catered for in our Organo-therapeutic Dispensary. A complete range of Gland substances is always in stock and prescriptions can be promptly and accurately dispensed.

THYROSEX CO.

This is one of our recognised formulæ. It is put up in Tablets and in Elixir form, each dose representing Thyroid sicc gr. $\frac{1}{4}$, whole Ovary sicc gr. $\frac{1}{2}$, whole Pituitary sicc gr. $\frac{1}{6}$. It is designed for the treatment of the sexual disorders of puberty and for the neuroses and psychoses of menstruation. Full particulars of this and other formulæ will be found in our brochure "PLURIGLANDULAR FUNCTION," which may be had on application to

Evans' Biological Institute, Runcorn.

What is ☆MONSOL☆ ?

MONSOL is a highly refined and efficient antiseptic prepared from Mond Oils.

MONSOL is a practical application of four essential principles, never before combined:—

(*a*) *Germicidal Power* (*b*) *Complete Penetration*
(*c*) *Harmless to Tissue* (*d*) *Healing Action*

Thus—**MONSOL** attacks all germs, whether surface or deep seated, without irritation or injury.

MONSOL products all combine these unique properties as no other preparations can do.

IN THE TREATMENT OF

TUBERCULOSIS

THIS form of treatment, entirely without danger, is suitable for application by any Medical Practitioner. The use of Dr. Jacobson's Solution has yielded noteworthy results in the treatment of the following different forms of Tuberculosis: Cutaneous, Pulmonary, Genito-urinary, Tuberculous Mucous Membranes, and Tuberculous Lymphatic Glands.

The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

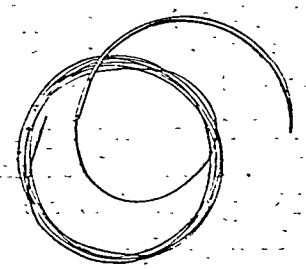
Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

"RYVITA CRISPBREAD"

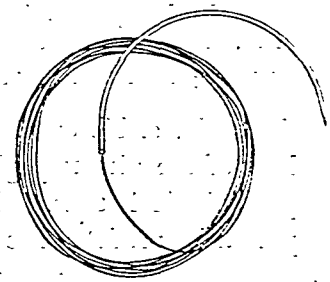
London Hospital Eyeless Needles

WITH L.H. CATGUT

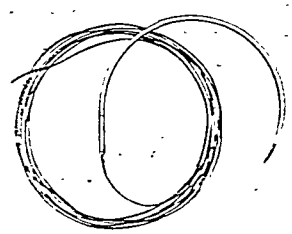
The London Hospital Eyeless Needles have been specially designed to avoid the doubling of the suture necessary in using needles with pierced eyes. They are fitted with tubular ends into which the sutures are firmly fixed, thus enabling the needles to be used with single strands. These needles are finely ground, sharp pointed and packed sterile in tubes for immediate use. Special precautions are taken to avoid any rusting of the needle after it has been packed.



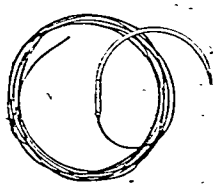
Curved Needle (Keith or Bantock) 3 side cutting edge. Sizes 3/0, 2/0, 0, 1, 2, 3. In boxes of 3 tubes, 4/6



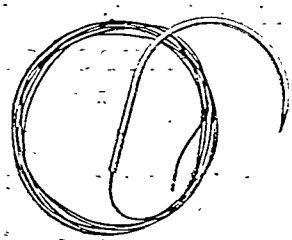
Curved Mayo Robson Stomach Needle. Sizes 4/0, 3/0, 2/0, 0, 1, 2, 3. In boxes of 3 tubes, 4/6



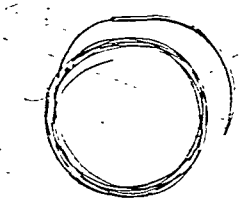
Moynihan's Model. In 3-tube box, 4/6



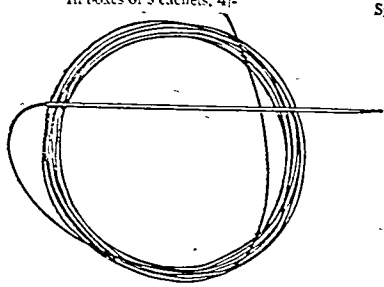
Ordinary Curved Intestinal Needle. Size 0. In boxes of 3 tubes, 4/6
In boxes of 3 cachets, 4/-



Symond's Round-Bodied Model. In boxes of 3 tubes, 4/6



Curved Ophthalmic Needle (also for plastic work). Size 6/0. In boxes of 3 tubes, 4/6



Straight Stomach Intestinal Needle. Sizes 4/0, 3/0, 2/0, 0, 0, 1, 2, 3, 4.
In boxes of 3 tubes with single needles, 4/6
" 12 " " " 16/-
" 3 " 2 needles 7/6

ANCIENT KELTIC NATIONAL ART AS EXEMPLIFIED IN THE ORNAMENTATION OF A BRONZE MIRROR FOUND IN GLOUCESTERSHIRE.—The metal mirror, of which the non-polished side is here reproduced, is of exceptional beauty. As in others of its kind, its engraved design consists of several large circles containing smaller eccentric ones and curvilinear ornamentation; the background is filled with cross-hatchings suggesting basket or mat work. The moulded handle is decorated with six enamelled circles in imitation of coral. The scroll work, so characteristic of Keltic art, is believed to have originated in the Greek palmette; this soon became transformed into a geometrical design worked out in curves, which do not at all suggest foliage, but yet remain very pleasing. S-shaped curves are a leading feature and may be seen in the accompanying mirror. This creation of the Keltic pioneer artists forms the basis of the designs evolved for the decoration of their beautiful repoussé work and, in association with other elements, borrowed and transformed, of the exquisite manuscripts of about 1000 years later. Their efforts resulted in a strikingly beautiful native art, unlike that of any other people. The human figure can hardly be said to enter into Keltic decorative art of the later Iron Age.

VERCINGETORIX, THE KELTIC PATRIOT, WHO LED HIS PEOPLE IN A SUPREME EFFORT TO RETAIN THE INDEPENDENCE OF A NATION RENOWNED THROUGHOUT THE ANCIENT WORLD.—Vercingetorix, the heir of the chiefs of the Arverni tribe, declared (Cæsar tells us) to the assembled people: "I will unite the whole of Gaul in a single will, and to that national unanimity the world itself will be unable to offer resistance." He did, for a time, unite the cities, calling upon their inhabitants, not in the name of his tribe, but in the name of Gaul. When, before the fortress and holy city of Alesia, the confederated tribes made their last magnificent stand and were defeated by Cæsar—after a nine years' campaign—the ruin of the Keltic domination was practically accomplished. Cæsar's victory was assured by the rivalry between the tribes forming the confederacy in Gaul, and when, a little later, they had to make their final decision for peace or war with the Latin power, they chose equality in dependence to Rome, rather than suffer a Keltic hegemony. The Kelts of Central Europe succumbed to the Romans and lost their independence in a series of defeats lasting from 16 to 10 B.C. Agricola brought about the submission of Great Britain, A.D. 78 to 85. Thus, with the exception of Ireland, the immense territory of the Kelts was absorbed into the Roman Empire and their pioneer work was gradually woven into the fabric of world-civilisation. Under the influence of the "Latin genius" and the "Roman Peace," there sprang up the strong Gallo-Roman civilisation, one of the most important stages in the growth of modern France. Later, Keltic Britain became Roman Britain, each phase contributing its share to the future.

TYPICAL SCHERING PRODUCTS

Arcanol

TRADE MARK

An excellent remedy in

COMMON COLD, INFLUENZA, TONSILLITIS and CATARRHAL AFFECTIONS GENERALLY.

Also as a prophylactic in influenza, catarrh of the upper respiratory passages, and in measles and scarlet fever to prevent complications such as otitis media.

Original Packings: **Tubes of 10 x 15 grain tablets.**

Veramon

TRADE MARK

The ideal analgesic for all forms of pain, especially in

HEADACHE, TOOTHACHE, DYSMENORRHŒA, INOPERABLE CARCINOMA.

'Veramon' is distinguished for its three excellent characteristics: it has an intense analgesic effect, does not affect the heart, and induces neither lassitude nor perspiration. It may, therefore, be taken at any time without inconvenience or fear of unpleasant secondary effects.

Original Packings:
Tubes of 10 and 20 tablets (6 grains).
Also in powder (1 oz. boxes).

Dose: 1-2 tablets according to severity of pain.

Medinal

TRADE MARK

After extensive clinical trials now regarded as the ideal soporific in

INSOMNIA, HYSTERIA, DEMENTIA, EXCITEMENT & DEPRESSION.

'Medinal' is readily soluble, and, therefore, easily absorbed and rapidly excreted. Safe and reliable in use and prompt in its effect. In appropriate doses it may be administered to children with absolute confidence in the paroxysms of whooping cough.

Original Packings:
Tubes of 10 tablets (5 & 7½ grains).
Also in cachets and powder.

Dose: 5-10 grains as required, in sweetened water or wine.

An Address
ON
SOME PROBLEMS CONNECTED WITH BENIGN ENLARGEMENT OF THE PROSTATE.*

BY
C. A. R. NITCH, M.S., F.R.C.S.,
SURGEON TO ST. THOMAS'S HOSPITAL, LONDON.

THERE are many problems connected with benign enlargement of the prostate which provide material for serious thought and discussion. Some of these problems have not yet been solved satisfactorily, and others are treated in different ways by many of the workers in this field of surgery.

Some writers still employ the term "hypertrophy," but this is incorrect, for hypertrophy of an organ implies an increase in size of all its component parts, whereas in the pathological prostate the enlargement is essentially glandular. It is now generally agreed that the condition, which for want of a better name is usually called "enlargement of the prostate," is due to an adenomatous formation, but the actual origin of the adenomata is as yet unsettled.

Before discussing the theories which have been advanced to account for these pathological changes, a brief reference to the anatomy and histology of the normal prostate is essential.

The gland is traversed by three canals, the urethra and the two common ejaculatory ducts, by which it is arbitrarily divided into five lobes, an anterior lobe in front of the urethra, two lateral lobes surrounding the urethra above the ejaculatory ducts, a posterior lobe below the ejaculatory ducts, and a so-called middle lobe between the upper part of the two lateral lobes. This arrangement is useful for descriptive purposes, but has no real anatomical basis, for the tissues composing the lobes are continuous with each other and quite inseparable.

The stroma of the prostate is formed of a felt-like mass of unstriped muscle, fibrous, and elastic tissue containing plicated tubular glands in its meshes. The portion immediately in front of the urethra, called the anterior commissure, is usually devoid of glandular elements, thus accounting for the absence of adenomatous tissue in this situation in the ordinary type of prostatic enlargement. When glandular tissue is present it may undergo pathological changes together with the rest of the gland, giving rise to annular enlargement, or rarely the change may be confined solely to it.

Beneath the mucous membrane of the trigone and the posterior urethra are four groups of glands which are quite separate and distinct from those of the prostate. Collectively they are called the submucous or accessory prostatic glands. One group lies beneath the trigone; a second around the internal meatus; the third and most important, distinctively named the periurethral or subcervical glands of Albarran, is situated in the submucous tissue of the prostatic urethra. This group consists of thirty or more branched tubules which open into the floor of the urethra between the neck of the bladder and the verumontanum. The fourth group is in the anterior wall of the urethra.

Of the many theories which have been suggested to explain this disease two only are worthy of consideration—the degenerative and the neoplastic.

The degenerative theory is based on the resemblance of the changes in the prostate to those in the female breast at the menopause. The microscopical appearance of the enlarged prostate is so similar to that of chronic lobular mastitis that frequently prostatic can only be distinguished from mammary tissue by its characteristic corpora amylacea. The similarity is so great that Henry Wade considers the disease should be called "chronic lobular prostatitis"; he attributes the change to alteration in a normal internal secretion associated with normal diminution of sexual activity.

The neoplastic theory is the one now more generally held, but even if this be the correct explanation the underlying cause of the adenomatous formation may still be due to a degenerative process.

There are two views regarding the origin of the adenomata; one is that they are true tumours of the prostate gland itself, and that their capsule is formed by the compressed but unaffected remains of the gland, analagous to an adenoma of the thyroid. The other view, held by many Continental writers, is that the adenomata arise in the periurethral glands, and that the prostate takes no part in their formation, but undergoes atrophy and compression as the tumours enlarge. The latter theory can account for the well-known freedom from adenomatous formation of the prostatic tissue below the ejaculatory ducts, since the periurethral glands do not extend below the verumontanum.

In this connexion it is an interesting fact that, owing to the escape of the posterior lobe, the verumontanum is seldom seen in the tumour removed by the suprapubic operation; its presence in an operation specimen would signify involvement of the prostatic tissue below the ejaculatory ducts, and consequent destruction of these ducts by its removal. Tumour formation in the accessory glands can also account for the pedunculated adenoma, the so-called middle lobe, overhanging the internal meatus, and also for the occasional small adenoma in the posterior wall of the prostatic urethra just below the internal meatus, which is sometimes, though rarely, the sole cause of obstruction.

Some writers, notably Motz and Péréarnau,[1] Papin and Verliac,[2] and Lendorf,[3] consider that the adenomatous change is limited solely to the periurethral glands, and that the prostate takes no part in its formation but is compressed and atrophied by the new growth. It is difficult to reconcile such a view with the naked-eye appearance of many enlarged prostates in the early stage which show adenomatous masses scattered irregularly throughout the lateral lobes at a considerable distance from the anatomical position of the periurethral glands.

And, again, the theory of a periurethral origin is untenable in the rare cases in which, after removal of an enlarged prostate, a second re-forms, identical with its predecessor in every respect, and as easily enucleable. Since all the periurethral glands must have been removed at the first operation the second growth can only have arisen from prostatic tissue surrounding the original adenomata.

In all probability both views are more or less correct, since in many cases the adenomatous change involves both the prostatic and the periurethral glands, but the practical application of these views is of importance to both patient and operator. If the adenomata are considered to be of prostatic origin then, after enucleation, all remaining portions of the prostate should be removed to prevent recurrence; but if, on the other hand, the change is thought to be limited solely to the periurethral glands, there is no necessity to remove any portions of prostatic tissue remaining in the wall of the cavity, and consequently the patient is saved the shock of a prolonged operation.

When the etiology of the disease is settled the correct surgical procedure will follow naturally, but until then it seems best to be content with the Freyer operation if, after digital enucleation of the tumour, the walls of the prostatic cavity are quite smooth; but if the walls are uneven, and contain irregular masses of small adenomata, an open operation should be performed and as much of the prostatic tissue removed as possible.

Since it is now universally agreed that, whenever possible, "prostatectomy" is the best treatment for benign enlargement of the prostate causing symptoms, the problems connected with it fall naturally into three groups: pre-operative, operative, and post-operative. It will only be possible to discuss some of these, but before doing so I will consider the cases which are clearly unsuitable for prostatectomy.

INOPERABLE CASES.

In general they belong to the class that constitutes bad surgical risks, no matter what the operation, and are those with advanced senile changes, gross arterio-sclerosis, pronounced chronic nephritis, organic disease of the heart or nervous system, diabetes, and obesity. Some of the

* Delivered before the Oxford Medical Society, November 8th, 1928.

conditions, such as glycosuria and obesity, can be improved so greatly by appropriate treatment that they cease to be serious operative risks, but on the whole the "prostatic" with these added complications is better treated by other means. Of these diathermy and deep x-ray therapy are at present under trial, but the results are uncertain.

Diathermy is applied by means of a special metal electrode, containing a thermometer, which is passed into the rectum and pressed against the prostate. The current is started, and slowly increased until the initial sensation of heat becomes one of discomfort; it is then reduced until the discomfort subsides, and is kept at this strength for twenty minutes. At this stage the temperature of the electrode will be about 111° F., but the temperature of the prostate will probably not be above 107° F. The treatment is repeated every few days, with gradually increasing intervals.

Deep x-ray therapy has been tried frequently, with results sometimes brilliant but more often disappointing; still, these methods are well worth a trial before the patient is condemned to a catheter life. If for any reason diathermy or deep x rays cannot be employed, or if they have been tried and failed, the only two possible procedures are permanent suprapubic drainage or the regular use of a catheter.

Catheterization is indicated when the patient is either very old or is obviously going downhill; when he is sufficiently intelligent to keep and use the catheter aseptically, or sufficiently well off to have it done for him; when permanent suprapubic drainage is advised and refused; and when nocturnal frequency is due to a large amount of residual urine. Apart from severe cystitis, nocturnal frequency is the complication which troubles the patient most, for his nights are so disturbed that he gradually becomes worn out from loss of sleep. Contrary to expectation it is not always dependent upon the quantity of residual urine, for some patients with a healthy bladder and a 6 oz. residuum may only be disturbed twice in the night, while others with only 2 oz. may have to urinate as often as six times. When nocturnal frequency is associated with less than 4 oz. of residual urine it is due either to cystitis, to highly acid urine, or to irritability of the bladder, and can be relieved by appropriate remedies; but when it is due to 6 or more ounces it can be greatly diminished by catheterization at bedtime, provided the patient abstains from drinking after 8 p.m.

Permanent suprapubic drainage is required when catheterization cannot be tolerated, or when it is difficult or impossible owing to the size and shape of the prostate; when it either causes haemorrhage or there are repeated severe haemorrhages unconnected with catheterization; when the patient suffers from relapsing subacute cystitis or from toxaemia due to chronic cystitis; and when nocturnal frequency is not relieved by catheterization. It is impossible to lay down any hard-and-fast rule, for each case must be judged on its merits and on the home conditions of the patient, but, speaking generally, in cases that are clearly inoperable catheterization should be given a trial whenever possible, for on the whole it causes less mental disturbance and less physical disability than the suprapubic tube. The cystitis that is the inevitable sequel of regular catheterization, no matter how carefully it is carried out, seems to cause very little discomfort; if it becomes troublesome permanent suprapubic drainage must be established.

The catheter should be passed about four times in the twenty-four hours when retention is complete; in the morning and at night when the amount of residual urine is about 10 oz.; and at bedtime only when the residual urine does not exceed 6 oz.

PRE-OPERATIVE PROBLEMS.

Age.

Enlargement of the prostate generally commences between the ages of 50 and 60, but the patient takes little notice of the early symptoms, regarding them as a necessary accompaniment of advancing years, and usually only seeks advice after the age of 60. By then the signs and symptoms are quite definite and an operation is clearly indicated. But if the case is seen when both enlargement and symptoms are slight, the question arises whether an immediate prostatectomy should be advised.

Provided the residual urine is not above 1½ oz., an operation at this stage is, in my opinion, unnecessary, for two reasons: first, in a certain proportion of cases the condition remains stationary for many years; and secondly, the operation may be very difficult, for in the early stages the line of cleavage between the adenomatous tissue and its prostatic capsule may be so ill defined that digital enucleation is impossible. The surgeon is then obliged to dissect away the affected tissues with scissors and forceps, an operation which requires considerable skill and experience. Therefore if a patient is seen in the early stage he should be watched carefully, and examined every six months for residual urine and renal efficiency, and operated on as soon as these indicate the onset of prostatic obstruction. In these early cases residual urine is the best sign of obstruction, and my rule is to operate when it amounts to more than 1½ oz.

Advanced age is no great bar to operation, provided the patient is otherwise healthy; the octogenarian often gives less anxiety than the man of 60, for he has only attained his years by the help of a sound constitution, and therefore his condition and resistance are relatively equal to those of the younger man. In my experience the most dangerous age is between 65 and 75, for by then obstructive symptoms have been present for some years, and the patient's kidneys have been so damaged by back pressure, and possibly by sepsis as well, that an operation may easily prove fatal.

It therefore follows that the optimum age for the operation depends entirely on the symptoms and not on the size of the gland. The approximately young man, with symptoms of prostatic obstruction without pronounced enlargement of the gland, is in as great need of surgical activity as the old man, with a large prostate causing practically no symptoms, is in need of masterly inactivity.

The Condition of the Patient.

Recovery after prostatectomy depends mainly on two factors—the renal function and the resistance to sepsis. Therefore before an operation is performed the renal function must be estimated very carefully both clinically and chemically. The clinical signs of a defective renal function are of the greatest importance and are often more valuable than chemical tests. The chief clinical signs of a defective renal function are a dry tongue, increased thirst, a sallow complexion, a poor appetite, and a distaste for meat. If, in addition, there is polyuria or oliguria the picture is complete.

The most reliable chemical tests are (1) the blood urea, and (2) the urea concentration test. In cases of enlarged prostate the blood urea test is the best, for the urea concentration test is apt to give a false impression by being on the low side if there is much residual urine. This can be overcome by collecting the urine with an indwelling catheter during the test, but the catheter may act as an irritant and so influence adversely the action of the kidneys.

In a healthy man on an ordinary diet the blood urea should range between 25 and 50 mg. per 100 c.cm. of blood according to age, and the urea concentration in the urine after a dose of 15 grams of urea in 100 c.cm. of water given on an empty stomach should rise from 2 per cent. in the second hour to 3 per cent. or over in the third hour. The value of the urea concentration test lies not so much in the actual quantity of urea excreted by the kidney as in the ability of the kidney to increase the concentration in each hour, and so give an indication of its capacity under a strain. Thus kidneys that yield, say, 1.9 per cent. in each of the three hours are not so efficient as kidneys that excrete 1.7 per cent., 1.8 per cent., and 1.9 per cent. in consecutive hours. In such a complicated structure as the human body chemical tests and clinical signs are often deceptive, but when both are taken in conjunction they give the most reliable indication that we have at present of the functional capacity of the kidneys.

Is it possible to fix a minimum limit to the urea concentration and a maximum limit to the blood urea beyond

either of which prostatectomy would endanger the life of the patient? In a previous communication[4] on this subject I gave the following answers, to which I still adhere.

"In my opinion the limits are a urea concentration of not less than 1.7 in the third hour, and not more than 50 mg. of urea in 100 c.cm. of blood, always provided that the clinical condition is satisfactory. When the clinical signs of a defective renal function are definite no chemical test should influence the surgeon in favour of an operation; and, conversely, if the clinical condition is a good one and the chemical tests are not too far below standard, he need not hesitate to operate."

In employing these tests as indications for or against prostatectomy the condition of the patient at the time they are made must be taken into consideration. When complete retention supervenes on long-standing obstruction the renal function will be greatly depressed, and, therefore, the tests will not indicate the real capacity of the kidney; but if they are made some days after the retention has been relieved and the general condition of the patient has improved they will be comparatively reliable.

The following two examples point to the importance of taking both clinical and chemical evidence into consideration.

1. A man, aged 65, with marked clinical and chemical signs of a defective renal function from long-standing prostatic obstruction, underwent suprapubic drainage for acute retention. Three months later the clinical picture was that of a man in moderate health but with a sallow complexion. The blood urea was 79 mg. per 100 c.cm. and the urea concentration did not rise above 1.5 per cent. in the third hour. At the end of another three months the results of the chemical tests were unchanged. Operation was therefore contraindicated. Six months later, after a brief illness, he died of uraemia.

2. A thin man, aged 56, looking very ill, had pyelonephritis, thick foul urine, and comple
duration, necessitating
was 40 mg. The urea
cent., and 1.6 per cent. in the three hours. Suprapubic drainage was performed and there was improvement with bladder lavage and vaccine treatment. Two months later the tongue was moist and clean, there was no thirst, a good healthy appetite was present, and the patient had gained 1 st. in weight. The blood urea was 46 mg. and the urea concentration 0.55 per cent., 1.25 per cent., and 1.5 per cent. in the three hours. The concentration was very low, but a steady rise indicated a kidney capable of withstanding a strain. The blood urea was normal for the age, and the clinical signs were excellent. Prostatectomy was followed by uneventful recovery and departure from hospital in six weeks. Three years later the patient was alive and well.

The first case was only a fair risk clinically and a bad one chemically, while the second was a good risk clinically and a poor one chemically. Experience has shown that life will be seriously endangered by prostatectomy if the blood urea is much over 50 mg. per 100 c.cm. of blood and the urea concentration below 1.5 per cent. in the second or third hour.

Since clinicians and biochemists have co-operated in gauging the renal function, deaths from uraemia after prostatectomy seldom occur, and, excluding pulmonary embolism, which is an ever-present danger, the greatest post-operative danger nowadays is sepsis in the form of suppurative pyelonephritis. MacAdam and Shiskin[5] have pointed out that the cholesterol content of the blood gives a fair indication of the power of resistance to sepsis, and that patients with a high blood urea and a normal blood cholesterol all recovered from prostatectomy, whereas nearly all those with a high blood urea and a low blood cholesterol died. The normal cholesterol content ranges between 0.13 per cent. and 0.19 per cent.; when it is below 0.13 the resistance to sepsis may be considered so low as to constitute a bad operative risk.

When there is no immediate urgency the dangers of post-operative sepsis can be diminished very greatly by a course of preliminary treatment. The mouth and teeth should be inspected and treated by a dentist if necessary. Moderate infection of the bladder should be treated by diuresis, urinary antiseptics, and lavage. In many cases three or four doses of an autogenous vaccine at intervals of five days will increase the patient's resistance to sepsis. When cystitis is severe the bladder must be drained suprapubically and irrigated continuously in addition to the measures already advocated.

For *B. coli* infections the best antiseptic is hexamine, but as it only acts in an acid medium the urine must be kept strongly acid with ammonium benzoate or acid sodium phosphate; for coccal infections hexyl-resorcinol (caprokol) is better than hexamine. It is interesting to note that patients with mild cystitis are less liable to post-operative sepsis than those with a healthy bladder, for their immunity has been raised by the infection.

Many prostatic patients suffer from flatulent dyspepsia and intestinal distension, which occasionally become acute after operation. These gastro-intestinal disturbances may be due to dietetic indiscretions, but more probably, in these cases, they are symptoms of defective kidneys. When due to the latter they will only subside when the back pressure on the kidneys has been relieved by preliminary suprapubic drainage, but if the kidneys are efficient they must be treated before operation by dieting, intestinal antiseptics, and judicious purgation.

OPERATIVE PROBLEMS.

Preliminary vaso-ligation is performed regularly by many Continental surgeons, but in this country it is only employed as a routine measure by a few. It is useful as a certain preventive of post-operative epididymitis, and is definitely indicated in all cases of pre-operative epididymitis. The question of procreation need not be considered, for sterility is usual after prostatectomy. Where impotence is a consideration—and this matter should always be discussed with the patient beforehand—vaso-ligation is contraindicated.

Without discussing the merits and demerits of the suprapubic and perineal routes, it is sufficient to say that for many reasons the suprapubic operation is the one usually employed in this country. To those who operate I would only emphasize the importance of a long incision in the abdominal wall. This allows the hand to be sunk between the recti, and enables the finger in the bladder to reach the prostate with the greatest ease. This free access to the prostate also permits enucleation with a gloved and therefore sterile finger, and dispenses with the necessity for a finger in the rectum.

Pre-operative Drainage.

In many cases, the number of which will probably increase with the experience of the surgeon, preliminary drainage is required for a varying period, either by means of an indwelling catheter or a suprapubic tube. Cabot[6] has pointed out that in the early stages of prostatic enlargement hypertrophy of the bladder wall is accompanied by congestion of its mucosa, a condition which lowers its resistance and may lead to serious post-operative infection. Preliminary drainage lessens the risk by relieving the congestion. Increasing obstruction, with its accompanying residual urine, leads to so-called back-pressure effects on the kidney, manifested, at the commencement, by dilatation of its pelvis and calyces, congestion of its parenchyma, and depression of its function, and ending in chronic interstitial nephritis, renal deficiency, and retention of urea in the blood.

Relief of back pressure by drainage of the bladder will restore the depressed or tired kidney to normal in a few days, but without this relief the sudden strain thrown upon it by such a severe operation as prostatectomy might inhibit its function altogether. The diseased kidney, provided its function is not too severely impaired, will also respond to the rest afforded by drainage in a remarkable manner, and many a case which at first sight appears hopeless will eventually recover to such an extent that a successful operation can be performed.

The use of the indwelling catheter is practically restricted to cases with slight renal deficiency or chronic urinary retention, for it cannot be employed when the bladder or kidneys are infected or when the prostate is bleeding. By some patients it is tolerated well, but in others it causes discomfort and irritates the urethra and bladder, and through them the rest of the urinary tract, and so does not give such complete rest to the patient or his kidneys as the suprapubic tube. It is difficult to keep the catheter surgically clean, and it always sets up a mild urethritis which must be a source of infection when the prostatectomy is performed. Its only advantage is that it leaves the operation field clear for the subsequent prostatectomy.

In nearly all cases in which primary prostatectomy contraindicated preliminary suprapubic drainage—in o

words, a two-stage operation—is preferable to an indwelling catheter. The suprapubic tube gives absolute rest to the patient and his urinary tract, does not irritate or infect his bladder, and enables him to move about in bed and sleep in comfort.

Pre-operative drainage is necessary (1) when there is complete retention or more than 4 oz. of residual urine, (2) for renal deficiency, (3) for severe haemorrhage from the prostate, (4) for urinary sepsis and cystitis, and (5) for the patient worn out by nocturnal frequency. It may be necessary for a week only or for several months, during which time the bladder, if infected, is treated by regular lavage, and the patient's immunity raised by an autogenous vaccine.

When the kidneys are defective the duration of drainage depends solely upon the improvement in the clinical condition and the chemical tests. If the deficiency is only due to renal fatigue from back pressure, drainage for a week or ten days will generally suffice, but when it is secondary to organic changes in the kidney drainage may be required for many months. If by nine months the blood urea has not fallen and the urea concentration is still below normal, there is no hope of improvement, and the patient must be content to wear the suprapubic tube for the rest of his life.

We all know that a tired horse will carry a load uphill if given a rest half-way, but if forced he will either jib or drop down dead. The same applies to a kidney tired out by prostatic obstruction: increase the load by a severe operation and it will cease work altogether; but if it be rested by means of suprapubic drainage, prostatectomy will eventually be possible and safe.

There are many surgeons who object to the two-stage operation on the grounds that it necessitates two anaesthetics and two operations, that enucleation is more difficult, and that a subsequent open operation is not possible. The first disadvantage is almost negligible, for the cystostomy can be performed under gas and oxygen with little or no discomfort. Enucleation may be more difficult, but not if the opening in the bladder is made high enough to permit of its enlargement downwards at the second operation. Lastly, an open operation *can* be performed, but requires care in separating the bladder from its adhesion to the abdominal wall.

However optimistic we may be, it is impossible to overlook the many dangers, both local and general, of prostatectomy, and there is no doubt that its gross mortality would be greatly diminished if the two-stage operation were more generally adopted. Only recently I heard of a case of acute retention in which an energetic operator performed an immediate prostatectomy. The patient made an uninterrupted recovery, but it is enthusiasm such as that which helps to make the gross mortality of prostatectomy in the London hospitals round about 20 per cent.[7]—a figure which is far too high.

In conclusion, let me summarize, by three hypothetical cases, the problems I have dealt with.

No. 1.—A man, aged 60, with prostatism, enlargement of the gland, and 2 oz. of clear residual urine. The tongue is moist, the appetite is good, and the complexion is clear. The blood urea is 35 mg. and the urea concentration over 2 per cent. A one-stage prostatectomy can be performed with safety.

No. 2.—A man, aged 68, with pronounced prostatic symptoms and 4 oz. of clear residual urine. The tongue is slightly dry, thirst is increased, and the appetite is not so good as it used to be. The blood urea is 45 to 50 mg. per 100 c.cm., and the urea concentration is 1.9 per cent. This is a clear case of tired kidney requiring rest for a week or ten days before prostatectomy, either by means of an indwelling catheter or a suprapubic tube. My choice would be the latter.

No. 3.—A man, aged 70 or more, with 10 oz. of residual urine, cystitis, and obvious clinical signs of a defective renal function. The blood urea is well over 50 mg. and the urea concentration below 1.7 per cent. A two-stage operation is imperative, with an interval of anything from three weeks to eight months between the first and second stages.

THE ISOLATION OF B. PARATYPHOSUS B FROM SEWAGE.

BY

J. D. ALLAN GRAY, M.B., B.Sc., M.R.C.P.Ed.

(From the Bacteriology Department, Edinburgh University.)

In the past the demonstration of specific pathogenic organisms in sewage and water has proved of the utmost technical difficulty. Methods of selective culture, however, have greatly facilitated the isolation of such bacteria (for example, typhoid-paratyphoid group) from material in which they are greatly outnumbered by other organisms, and these methods have been most successfully applied in the bacteriological examination of faeces from cases of enterica (Browning, Gilmour, and Mackie, 1913; Mackie, 1917; and others). A further development has been the application of selective methods in the examination of sewage and water. Even though the typhoid-paratyphoid bacilli are present in communal sewage containing the excreta of diseased persons or carriers, dilution must render them exceedingly scanty in proportion to other bacteria, and it might be expected that the greatest difficulty would be experienced in demonstrating them even by selective methods. The same would apply to water. The success obtained by Wilson (1928) in demonstrating *B. typhosus* in Belfast sewage by his method of selective culture marks a great advance in this branch of bacteriological investigation. I have applied Wilson's technique along with other methods in the examination of sewage in Edinburgh, and the object of this communication is to record the results of the investigation, which seem of considerable interest and importance from the point of view of public hygiene.

Methods.

The following cultural methods were employed.

1. The "*glucose-bismuth-sulphite-iron-brilliant-green medium*" introduced by Wilson and Blair (1928) and termed by them medium B. The rationale of the use of this medium is explained by Wilson as follows. In the presence of a certain excess of sodium sulphite, bismuth sulphite tends to suppress the growth of most coliform bacilli; when, in addition, a fermentable carbohydrate is present, *B. typhosus* reduces the sulphite to a sulphide, the latter reacting with the iron salt to form iron sulphide, which blackens the colonies. The brilliant green enhances the selective action of the medium for organisms of the enterica group.

With a view to obtaining definite knowledge of the colony appearances of various organisms on this medium, strains of *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, a typical *B. coli*, *B. proteus* and *B. fluorescens* types were plated out. The growths obtained varied very considerably in appearance with the strain of organism and the period of incubation.

B. typhosus produced, after twenty-four hours' incubation, minute clear discrete colonies which after a further twenty-four hours became jet black, or, more commonly, a bright green colour.

B. paratyphosus A was similar to *B. typhosus* except that none of the colonies were black.

B. paratyphosus B. After twenty-four hours' incubation all the laboratory strains of this organism produced clear discrete colonies each 1 mm. in width. After forty-eight hours' incubation these colonies became bright green. In addition, however, one of the strains produced black colonies with a metallic lustre, which after four days' incubation were 6 mm. in diameter and had a raised greyish centre.

B. coli produced, after twenty-four hours, colonies similar to those of *B. typhosus*. After further incubation most of these became bright green; some which grew slowly assumed a black colour, but without metallic lustre.

Some strains of *B. proteus* were inhibited for twenty-four or forty-eight hours, but later produced green colonies varying slightly in shade.

B. fluorescens was also inhibited for twenty-four or forty-eight hours, but later produced dull green colonies, which eventually became brown.

When this medium was inoculated with actual samples of sewage it was found that it inhibited the growth of a very large number of the coliform organisms present. The colony appearances of any one organism, however, varied; thus, "enterica" group may be present in a given sample of sewage and yet may not necessarily produce colonies with a specially distinctive appearance.

Contrary to Wilson's findings, I found that lactose-fermenting organisms might produce black colonies on the B medium. For this reason subinoculation of such black colonies on Wilson's modification of the Endo medium, in which saccharose replaces the lactose, was deemed less suitable than on one in which saccharose was present in addition to the lactose. The presence of the second sugar does not appear to influence any action an organism may have on the other substance. MacConkey's medium containing both sugars was found to give sharper demarcation between pale and pink colonies than the corresponding Endo

medium. Any black colony on medium B which, on subculture, produced a pink growth after twenty-four hours' incubation on the double-sugar MacConkey medium was discarded. Owing to the fact that *B. proteus* and *B. fluorescens* produced pale growths, representative pale colonies on the double-sugar medium were first subinoculated on slopes of Loeffler's inspissated serum. Two days later, if the serum was unliquefied, the morphology and cultural, fermentative and biochemical reactions of the colony were examined.

2. *The brilliant green enrichment method introduced by Browning, Gilmour, and Mackie (1913).* A series of tubes of peptone water containing varying amounts of brilliant green were inoculated and incubated for twelve hours; subinoculation from each tube on a MacConkey plate was then made. The variability in the optimum concentration of brilliant green for the selective enrichment of the enterica group necessitated the use of varying amounts of the dye. The actual amounts of brilliant green used for 5 c.cm. of peptone water were: (1) 0.2 c.cm., (2) 0.3 c.cm., (3) 0.4 c.cm., (4) 0.5 c.cm., (5) 0.6 c.cm., (6) 0.7 c.cm. of a freshly prepared 1 in 10,000 solution, and it was found that the best results were obtained from the tubes containing 0.4 c.cm. and 0.5 c.cm. of the dye.

3. *Rakieten and Rettger's modification of the original brilliant green method.* In this method, prior to the addition of the brilliant green 0.4 c.cm. of a phosphate buffer solution was added to each tube and the reaction adjusted to a *p*H 6.5. The buffer is added to prevent alkalinization of the medium during growth, with the consequent precipitation of the dye.

4. *MacConkey's medium.* In addition, the samples of sewage were plated directly on MacConkey's medium. It was found impossible to isolate paratyphoid bacilli in this way owing to overgrowth by lactose-fermenting organisms.

5. *Wilson and Blair's lactose-bile-salt-brilliant-green medium* (for the isolation of *B. paratyphosus* B) was not found sufficiently inhibitory to coliform organisms, and did not yield sufficiently characteristic colonies in the case of the enteric group. It was therefore not used for sewage.

Examination of the Sewage.

Six samples of sewage were taken in sterilized bottles first from main sewers of four different districts of the city, which may be named A, B, C, and D for reference purposes.

Each of the *selective* methods elicited the presence of *B. paratyphosus* B in the sewage from District A on two of the three occasions on which it was examined. In agglutination and agglutinin-absorption tests each of the strains of the organism corresponded exactly with *B. paratyphosus* B (Schottmüller), controls being performed in which *B. paratyphosus* B serum was treated with emulsions of the homologous organism and *B. aertrycke* and its agglutinating properties then tested with these organisms.

A considerable number of the black colonies on the B medium had to be subcultured and examined further to enable the paratyphoid bacilli to be picked out. This was probably due to the fact that, according to Wilson and Blair (1928), *B. paratyphosus* B behaved on bismuth sulphite media more like a reducing *B. coli* than *B. typhosus*, with the result that the plates had to be incubated for more than twenty-four hours before colonies of *B. paratyphosus* underwent blackening. Organisms other than those of the enteric group therefore had time in which to develop a black coloration.

Since the main sewer of District A contained *B. paratyphosus* B the contents of each of the various tributary sewers entering it were next examined on two occasions. These tributary sewers were numbered from 1 to 7, starting with the most outlying one and ending with the side sewer entering the main sewer nearest to the latter's termination. It was found that of these seven tributaries three contained *B. paratyphosus* B, the identity of the organism being established as before by serological tests. Sewers Nos. 4 and 7 were positive on both examinations, but No. 5 on the second examination only. Thus, in all, *B. paratyphosus* B has been isolated by selective methods from seven out of the twenty samples examined.

The numbers of black colonies on medium B from the same amounts of different samples varied greatly even when the samples had been obtained at approximately the same hour of the same day and therefore could not have been unequally affected by rainfall. For instance, in the first sample obtained from No. 4 there were 209 black colonies on the B plates inoculated with 2.5 c.cm. of the sewage, while a similar amount of the sample from No. 2 obtained at approximately the same hour of the same day showed only 56 black colonies. It may be noted here, too, that the sample from No. 4 was peculiarly rich in *B. paratyphosus* B, for these 209 colonies were all identical in appearance with eleven colonies examined, ten of which were finally identified as *B. paratyphosus* B. The unevenness in the distribution of the organisms producing black colonies on the bismuth sulphite media in one sample rendered useless any attempt at making a quantitative estimation as to the minimal amount of sewage from which *B. paratyphosus* B could be isolated.

Survival of B. paratyphosus B in Sewage.

Experiments were also performed with a view to determining the period of survival of *B. paratyphosus* B in the sewage. All the samples from the main sewers were examined one, two, and four days subsequent to their withdrawal from the sewer in a manner identical with that in which they were examined on arrival at the laboratory as above described. In no instance was *B. paratyphosus* B isolated, so that the evidence pointed to a short period of survival of the organism in sewage.

Comparison of the Selective Methods Employed.

It is difficult at the present time to draw a definite comparison between the selective methods employed. The results obtained by their use varied considerably. In some cases positive results were obtained by each method, but it was found that any one of the three selective methods might fail to reveal the presence of the paratyphoid bacilli, while at least one of the other methods gave positive results.

The plates of Wilson's medium when inoculated with the last four samples taken from the side sewers remained completely sterile. As far as could be ascertained the medium for this batch of plates was prepared in a manner identical with that adopted for the making of the previous samples of media. In the earlier tests the B medium had revealed the presence of *B. paratyphosus* B in every sample of sewage in which the organism had been found by the brilliant green enrichment methods. Wilson and Blair assert that "the bismuth sulphite media enormously increase the chances of isolating typhoid bacilli," and the same undoubtedly holds good for the paratyphoid bacilli.

The brilliant green enrichment methods, although usually effective, were found on occasion to give negative results, when the B medium revealed paratyphoid colonies. In the first sample taken from tributary sewer 4, plates of B medium inoculated with 2.5 c.cm. of the sewage yielded 220 suspicious colonies, ten of the eleven examined proving to be *B. paratyphosus* B; neither of the enrichment methods showed the presence of the organism at all. This was to a large extent due to overgrowth by *B. fluorescens* and *B. proteus* types. Many of the pale colonies, too, were found on identification to be types of Morgan's bacillus. After considerable experimentation it was considered that Rakieten and Rettger's modification did not produce results better than the original method, and in the first sample from side sewer 7 it proved negative while the original method gave a positive result.

Loss of Motility of B. paratyphosus B.

An interesting feature elicited was the loss of motility of certain of the laboratory stock strains of *B. paratyphosus* B, as well as of some of those isolated from the sewage, when grown on medium B. Their motility, however, returned on subinoculation into ordinary nutrient media. Loss of motility of *B. typhosus* in the presence of brilliant green was also observed by Rakieten and Rettger.

DISCUSSION OF THE FINDINGS.

The results are of special interest as they confirm (for another city in the British Isles) Wilson's finding of an enteric group organism in communal sewage.

So far samples from only four out of the twenty-three districts of the city have been examined, and all those found to contain the paratyphoid bacilli had been taken from sewers in one and the same district. At an early stage of the work enteric organisms were isolated from the main sewer of this district, and all sixteen samples of the second series were obtained from the same district, with

a view to ascertaining whether the organisms were limited to sewage from a localized area. The work was then discontinued owing to the onset of extremely cold and wet weather. The question of the distribution of enteric organisms in the other districts of the city therefore remains to be determined.

Since the city of Edinburgh is at present comparatively free from enteric fever, the presence of *B. paratyphosus* B in the sewage of a particular district is in all probability mainly due to resident "carriers," and it is significant that this district was the locus of an outbreak of paratyphoid B fever in 1927. The medical officer of health of Edinburgh, in his report for that year, has made special reference to sewage as a source of this outbreak. Owing to the inability of the main sewer of the district to carry off the excessive volume of water during a flood, two of the byre steadings concerned in the outbreak were inundated with overflow from drains and sewers near-by. It seems not unlikely that the milk may have become infected through contamination of the premises in this way. Of course, for the infection to have been thus transmitted the sewage dammed back into the byres must not only have contained the specific organism at the time in question, but must also have been fairly heavily contaminated in view of the dilution with the flood water. The presence of a "carrier" actually at or near the byres would, of course, increase the probability of this happening, but it must not be forgotten that such a "carrier" may have introduced the infection by more direct contamination of the milk vessels.

The suggestion is put forward that, by ascertaining the points of entry of the *B. paratyphosus* B into the various tributaries of the main sewers found to contain paratyphoid bacilli, "carriers" of the organism might be located with the help of public health officials. Criticism may be raised that the strains of *B. paratyphosus* B (Schottmüller) isolated might be of animal origin, for Jordan (1923) has recorded strains of porcine origin belonging to the Schottmüller type. In District A of the city, from which the sewage in question was obtained, there are a number of piggeries, but the rarity of strains of porcine origin and the small proportion of excretal matter from such piggeries in the communal sewage would render unlikely the possibility of these strains coming from such a source. The excreta from several of the piggeries in the district have been examined by the same methods as those which were applied to the samples of sewage, but no paratyphoid bacilli have thus far been isolated. The question, however, is still receiving attention.

SUMMARY.

1. *B. paratyphosus* B (Schottmüller) has been isolated by selective methods from 7 out of 20 specimens of sewage from the city of Edinburgh. Seventeen of the samples, including all the positive ones, were from one district, and were selected in view of the preliminary finding of the organisms in the main sewer of the district.

2. Comparison has been made of three selective methods: (1) Wilson and Blair's "glucose-bismuth-sulphite-iron-brilliant-green medium"; (2) Browning, Gilmour, and Mackie's brilliant green enrichment medium; and (3) Rakieten and Rettger's modification of the second. Any one of the three methods may fail to detect paratyphoid bacilli isolated by the others. Wilson and Blair's method has the advantage that it is a direct plating method, and the enrichment methods have the disadvantage that they tend to permit overgrowth of *B. fluorescens* and *B. proteus* types, which are prevalent in sewage.

3. The organisms are probably very unevenly distributed in the sewage.

4. No evidence has been obtained that paratyphoid bacilli survive for long periods in sewage.

5. The danger of the presence of *B. paratyphosus* B in sewage is discussed, particularly in relation to an outbreak subsequent to the flooding of two byres in 1927, and it is suggested that this method could be adopted in the tracing of "carriers."

6. The possibility of the strains of *B. paratyphosus* B isolated being of animal origin is considered unlikely.

I desire to express my thanks to Professor T. J. Mackie for his advice and guidance in the course of this investigation, and to the burgh engineer and his staff for their willingness in providing samples of sewage.

TORSION AND STRANGULATION OF A HYDATID OF MORGAGNI.

BY

D. A. ABERNETHY, B.M., B.CH.OXON, F.R.C.S.ED.,

HONORARY ASSISTANT SURGEON, RADCLIFFE INFIRMARY, OXFORD.

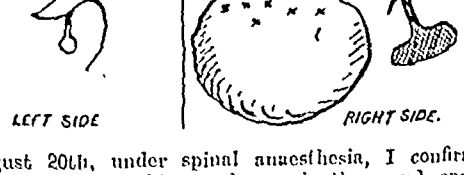
I RECENTLY removed a strangulated and thrombosed hydatid of Morgagni which was giving rise to symptoms resembling those of mild appendicitis. Such a lesion must be very uncommon, and the following details would therefore seem to be of general interest.

A woman, aged 33, who complained of right-sided abdominal pain, was seen by me on August 6th, 1928. She stated that during the previous three weeks she had had several attacks of pain in the right iliac fossa. This pain was colicky in character, and had become so much worse during the last three days before she came to hospital as to provoke vomiting on several occasions.

Her menstrual history was as follows. The last regular period was on May 8th; two months' amenorrhœa followed, after which she experienced irregular losses containing clots, but no obvious products of conception. She had had three pregnancies, all of which resulted in healthy children at full term. In 1921 she had an attack of pain in the right lower abdomen, which was diagnosed as appendicitis, but cleared up without operative intervention. She had never had any similar pain until the present time.

On abdominal examination pain and tenderness were found low down in the right iliac fossa above the lateral third of Poupart's ligament, and slight rigidity over the lower right rectus muscle; no other abnormality was noted. The temperature and pulse were both slightly raised—99.4° F. and 80.

A vaginal examination revealed that the cervix was soft; the external os admitted the finger-tip; the body of the uterus was normally anteverted and anteflexed, and was enlarged to the size of a nine weeks' pregnancy. On the left side there was palpable an ovarian cyst, about two inches in diameter; on the right side the adnexa were not easily palpable, and rather immobile. A diagnosis was made of incomplete abortion, possibly due to right-sided oöphoritis secondary to inflammation of a pelvic appendix.



On August 20th, under spinal anæsthesia, I confirmed these findings by a further bimanual examination, and explored the uterine cavity, from which were removed several necrotic fragments of placental tissue. Pelvic laparotomy was then performed in order to investigate the condition of the appendix and the adnexa on the right side. The appendix was long and showed some slight thickening, but was not markedly abnormal; there was an ovarian cyst on either side, and hanging from the fimbriated extremity of the right tube was a reniform body, black in colour, and measuring about 3/4 by 1/4 by 1/4 inch, in the position in which one would expect to find the hydatid of Morgagni. It showed two well-marked twists in its pedicle, and was much larger than the normal hydatid on the left side. The peritoneum covering it was thick and lustreless. This body was removed without salpingectomy, and appendicectomy was performed.

The appendix, examined subsequently, showed signs of some chronic but no recent inflammation. The reniform body, on pathological examination, was pronounced to be a strangulated hydatid

of Morgagni, and is preserved in the Pathological Museum of the University of Oxford. The patient made an uninterrupted recovery.

This case has seemed worthy of record rather on account of the rarity of the condition than of its clinical significance. I have failed to find any allusion to this lesion in the literature of the subject, nor do any cases appear to have been published recently, at least in this country, America, or on the Continent. It would be interesting to know whether previous cases have been observed but not published.

The description of the original colicky pain was suggestive of a uterine origin, and was attributed to the incipient abortion, but the severe right-sided pain which induced vomiting did not begin until the abortion was almost complete—that is, three weeks later—when the uterus contained nothing but a few necrotic fragments. It seems not improbable that this pain was due to the stretching of the covering peritoneum produced by the engorgement of the strangulated hydatid. No cause was found for the torsion. The ovarian cysts were both simple follicular cysts following an old perioöphoritis, which had produced on the right side a few inconsiderable adhesions; the appendix presumably could have had nothing to do with the condition.

TORSION OF THE APPENDIX OF THE TESTIS (HYDATID OF MORGAGNI).

BY

L. R. BROSTER, D.M., M.Ch.Oxon., F.R.C.S.,

ASSISTANT SURGEON, CHARING CROSS HOSPITAL; SURGEON, QUEEN'S HOSPITAL FOR CHILDREN;

AND

RALPH COYTE, M.B., B.S.Lond., F.R.C.S.,

ASSISTANT SURGEON, ALL SAINTS' HOSPITAL, QUEEN'S HOSPITAL FOR CHILDREN, AND PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.

THIS condition appears to be one of rare occurrence, in view of the fact that we can find no reference to it in standard textbooks or recent English literature. It is therefore of interest that during the year 1928 we have each operated on two such cases at the Queen's Hospital for Children. All four cases we were able to diagnose before operation.

In each case the patient was a boy aged 12 years, and had not attained puberty. The cases demonstrated a marked similarity of onset and subsequent history, and the following case may be taken as typical.

The patient, five days before admission, complained of sudden pain in the right testis, without history of trauma. There was no vomiting or constitutional disturbance. Pain continued in spite of rest in bed, and on attendance at hospital the following condition was observed. There was swelling and tenderness of the whole testis, the skin of the scrotum was reddened and oedematous, and the spermatic cord was thickened throughout its length. On palpation a small body, about the size of a pea, was felt lying between the upper pole of the testis and the globus major. This small swelling was exquisitely tender, and not freely movable.

At operation the tumour was found to be of a deep plum colour, and obviously full of blood clot. There was marked oedema of the spermatic cord. The tumour was in the position of the hydatid of Morgagni, and had a pedicle, which had obviously undergone torsion. The pedicle was ligatured and the hydatid removed. On microscopic examination the following report was obtained: Section shows organizing blood clot undergoing degeneration; here and there are cystic spaces lined with flat unciliated epithelium.

The patient was immediately relieved after operation, and made an uninterrupted recovery.

In one case of five days' duration the hydatid showed signs of commencing sloughing. Another case was brought to the hospital six hours after onset, and already demonstrated oedema and reddening of the scrotal skin. Two cases occurred on the right side, and two on the left.

In conclusion, we wonder if this condition is really of rare occurrence, or whether these cases are frequently treated as orchitis of unknown origin, and left until the twisted hydatid sloughs, and resolution eventually occurs; presumably a painful and protracted process.

VARICOSE VEINS: THEIR MODERN TREATMENT BY SCLEROSING INJECTIONS.

METHODS AND TECHNIQUE OF "SICARD AND GAUGIER" AS PRACTISED AT THE HÔPITAL NECKER, PARIS.

BY

P. KENNEDY MURPHY, M.A., M.D., B.Ch.,

LATE TEMPORARY ASSISTANT SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM.

SCLEROSING injections for the treatment of varicose conditions have emerged successfully from the trial stage and are now almost universally regarded as being safe, effective, and the treatment of choice for varix.

The object of treatment is to obliterate the whole or part of the veins concerned in the superficial circulation of the limb—namely, the internal and external saphenous veins and their branches. These veins run in the subcutaneous tissue and have no support except their own walls; when the superficial circulation is occluded the blood returns by the deep veins, which are well supported by the muscles of the leg.

The principal points of interest to the doctor who intends taking up this work are: (1) methods of selecting cases suitable for treatment; (2) technique of injection; (3) choice of sclerosing fluid and strength of dosage; (4) number of injections necessary and interval between each; (5) the pathological effects of injection on the vein; (6) after-effects and possible complications. The advantages of this method are that when properly administered injections are safe and certain in their results, cause little pain or discomfort, and the patient need not lie up.

A bewilderingly large literature on injection treatment is being added to daily; most of it is interesting and helpful, but a lack of agreement on the essential points just mentioned is unfortunately a frequent and salient feature. In the confusion thus caused many who wish to take up this work find it difficult to decide what procedure to follow. Ill results of a serious character following treatment are being reported with increasing frequency, and are mainly due to defective technique and lack of authoritative knowledge on the subject. As it is universally conceded that it is to Professor Sicard of Paris we are indebted for establishing, in 1916, the treatment of varicose veins of the limbs by injection as a safe and effective procedure (the idea had been experimented with unsatisfactorily for seventy years), those who are about to adopt this method of treatment for the first time will be wise to follow the methods of this, the greatest authority, or at least adopt those methods as a sound basis on which to found their own experience. (The principle of employing sclerosing fluids for treatment of varix was, however, first successfully put into practice by British doctors, but only for the treatment of haemorrhoids. Morgan and Colles of Dublin were the pioneers seventy years ago, and Mr. Swinford Edwards, whose house-surgeon at St. Mark's Hospital it was my privilege to be, first introduced the method to this country, his article in the *British Medical Journal* of October 13th, 1888, being still one of the most instructive.)

Sicard's opinions and advice on this subject are as authoritative as Ehrlich's on the treatment of syphilis by arsenical injections. His special clinic at the Hôpital Necker, Paris, is of world-wide reputation, and here he and his colleagues, Gaugier, Paraf, Forestier, Haguenau, and Lermoyez, have treated many thousands of cases, necessitating hundreds of thousands of injections, with excellent results and without a single serious mishap.

Sodium salicylate is the sclerosing injection they recommend, and since the publication of their results many other workers, acknowledging their indebtedness to Sicard's work, have endeavoured to find, if possible, an even more effective chemical for injection: quinine (Génévrier), mercury biniodide (Montpellier and Lacroix of Algiers), glucose (Nobl), the citrate (Troisier), chloride (Linser), and carbonate of sodium, and other solutions, all have now their own advocates. Every new sclerosing fluid recommended by any authoritative worker is given an

extensive trial in a series of cases at the Hôpital Necker, and compared with a series of cases treated by sodium salicylate, and many thousands of injections of the solutions just mentioned have been given in this fashion. From this unique experience Sicard and his colleagues are of opinion, whilst appraising the work of the distinguished men just mentioned, that sodium salicylate is the most effective, safest, and gentlest in its after-effects, of all injections.

Thanks to the courtesy of Professor Sicard and Dr. Gaugier it was my privilege to assist on many occasions at the injection of a large number of cases at the Hôpital Necker, and I am deeply indebted and grateful to Dr. Gaugier for his kindness in explaining to me their methods and technique, which I have since followed with most gratifying results. I had for many years previously had much experience of sclerosing injections in the treatment of haemorrhoids, both at St. Mark's Hospital and in private practice, and had given many thousands of intravenous arsenical injections, mainly at the London Lock Hospital, so that the acquisition of the technique presented few difficulties. These methods and technique, which I will state as briefly as possible, are as follows.

1. *Selection of Cases.*

Every patient should first undergo a complete general examination—heart, kidneys, etc.

Contraindications to Injection.—(*a*) Obstruction in the veins of the deep circulation is the most important. To ascertain if the deep circulation is obstructed, fasten a tourniquet below the knee and make the patient walk round the room. If no obstruction is present the swollen veins empty themselves into the deep circulation, and then appear almost flat, but should occlusion exist the superficial veins of the leg become more swollen and the leg painful. Should this test be neglected and injection given when the deep circulation is occluded a most painful and oedematous condition of the limb, coming on rapidly, due to stirring up of the phlebitis, and lasting many weeks, may result. Phlebitis of the deep veins, of old or recent origin, is the commonest cause of obstruction, and phlegmasia alba dolens is the commonest cause of deep phlebitis. Marked dilatation in the veins of the pubic area when present is usually a relic of this condition, and should put one on guard. (*b*) Arteritis (intermittent claudication) and any condition in which embarrassment of the circulation already exists. The clinical history is the best guide in the diagnosis of intermittent claudication; in this condition the patient suffers whilst walking and is relieved on standing, whilst the varicose patient suffers while standing and is relieved on walking. (*c*) Cardiac insufficiency of any degree and advanced kidney disease are the next most important contraindications. When other cardiac lesions exist, and when albumin or sugar is present even in small amounts, injections should be administered with great caution. (*d*) Excessively high blood pressure. (*e*) Extreme old age. (*f*) Pregnancy is a contraindication, because varicose veins associated with this condition either undergo spontaneous cure or get considerably better soon after delivery, but especially because it has been demonstrated by Bar that the blood of pregnant women is hyperfibrinous, and therefore predisposed to phlebitis. Marked vulvar varicosities can, however, be injected, as they may be a serious complication at the time of delivery. (*g*) Multiple uterine fibromata may also be a contraindication.

2. *Technique of Injection.*

The patient stands on a chair beside a table, the latter being provided with a handrail on which the patient leans (it is now possible for special tables to be obtained). The upright position renders the veins tense, a tourniquet being useless. The most prominent point of the most prominent vein of the leg below the knee is selected; midway between ankle and knee is, as a rule, the best part to choose. The injection must be completely intravenous, and made with the usual aseptic precautions of sterilizing skin, needle, etc. The syringe should be of light weight: a small all-glass 5 c.cm. syringe is best. The injection, as a rule, is best made in two stages, especially when the veins are not very large. It is well to have two of the small glass syringes, one empty with needle attached, the other without needle and filled with solution. The size of the needle should be that of the ordinary small hypodermic syringe, and the point should be very short. The vein is entered with the needle attached to the empty syringe, the patient standing. To ascertain if the needle is in the vein the piston is slightly withdrawn, when blood should enter the syringe. When blood enters the syringe (and not before) the syringe is detached from the needle, and whilst the needle is still in the vein the patient is made to lie down. When the patient is lying down (not before) the syringe filled with solution is attached to the needle in the vein; injection should be done slowly, especially as regards the smaller veins, otherwise painful spasm or rupture, leading to escape of fluid and subsequent ulceration, may occur. The standing position makes it easy to enter the vein. The recumbent position causes the vein to empty itself, and if the solution is injected then it gets into immediate and intimate contact with the endothelium. The needle is allowed to remain in the vein for one minute at the end of injection, and is then briskly withdrawn, a tampon of cotton-wool being rapidly pressed over the point of exit. This is important, a common cause of pain, local discoloration, and ulceration after injection being the slow withdrawal of the needle, which allows some of the injected solution to escape into the surrounding tissues. Should the veins be large the injection can be made in one stage, with the patient lying down.

There are two causes of pain at injection; the first is injecting the fluid outside the vein. The patient complains immediately of pain and burning at the site of injection. The needle should be withdrawn at once and another part of the vein selected. The second kind of pain is cramp-like or stinging, and may extend the whole length of the limb. It usually comes on towards the end of, or immediately after, injection, and is due to vasomotor disturbance caused by the solution irritating the endothelial lining of the vein and thus exciting the sympathetic. It lasts about a minute or two, is quite bearable, and does not recur. This pain does not always happen, but does so frequently. The patient should be warned to expect it, and assured that it will only last a minute or two and will not return. It is best to keep the patient lying down for about ten minutes after injection, as muscular action is liable to aspirate the fluid from the superficial circulation into the deep. In the region of the malleolus and over bone the injections should be small in amount and of weak strength, otherwise pain and oedema lasting some weeks may result. As only large varicose veins are easy to inject, considerable practice in intravenous technique is advisable before consistently successful results can be attained.

3. *The Sclerosing Fluid and Strength of Dosage.*

Sodium salicylate is the injection of choice. It should be a chemically pure and colourless solution. Solutions which have turned violet should be rejected. The salicylate should be made up in specially hard glass which cannot be acted on by the solution. The first injection should consist of 2 c.cm. of a 20 per cent. solution, and this amount and strength should not be exceeded at a first visit. Two days later the second injection is given, the amount and strength of which depends on the effect produced by the first. The injections are gradually increased in strength and quantity, 3 c.cm. of 30 per cent. being given on the second and 4 c.cm. of 40 per cent. on the third occasion. One should never exceed 6 c.cm. in amount and 40 per cent. strength at one visit. The action produced by the preceding injection is the true guide to the strength and amount of each succeeding injection, and a little practical experience will soon teach the surgeon much on these points. The strength and amount of dosage should, however, be increased as rapidly as possible when no contraindications exist, in order to hasten the irritation of the endothelial lining of the veins; small and weak doses frequently repeated only harden the walls of the vein without causing obliteration, and the veins thus hardened will offer a great resistance to subsequent injections even though those injections be numerous and strong; this is the commonest cause of failure to procure obliteration. It is inadvisable to add novocain or any other

analgesic to the salicylate with the object of diminishing the cramp-like pain. The novocain renders the fluid anaesthetic, and in the event of the solution being injected by mistake into the perivenous tissues, the absence of pain may cause the doctor to be unaware of his error and subsequent ulceration will be the result.

4. *Number of Injections Necessary and Interval between each.*

This depends on the number, extent, tortuosity, and calibre of the veins, and on whether one or both limbs are varicose, five or six injections as a rule being sufficient for each limb. Three to five inches of vein on an average are usually occluded with 4 c.cm. of a 40 per cent. solution, but much more is not infrequently obliterated; two injections of 5 c.cm. of 40 per cent. solution are sometimes sufficient to obliterate completely the internal saphenous vein.

There is no fixed rule as to interval between injections. If both limbs are affected the patient may attend daily, each limb being injected on alternate days, a different segment of vein being selected each time, depending upon the amount of reaction of the previous injection. With experience the necessary knowledge on these points will soon be acquired.

5. *Effects of Injection on the Vein.*

The manner in which chemical injections cause obliteration of veins is different from that in which infective phlebitis is produced. The immediate effects of injection are vasomotor, especially vaso-constriction (through stimulation of the sympathetic which supplies the smooth muscle regulating the calibre of veins), pallor of the part, and a "goose flesh" appearance of the skin. A chemical endovenitis with thrombosis occurs during the first hour, and some hours later the inflammation spreads to all the coats of the vein and even outside the vein (periphlebitis). This has been proved (Jentzer and Askanazy) by adding collargol to the salicylate solution and then injecting the mixture. Part of the vein was then removed, the collargol being found in all tunics of the vein and seen in the tissues outside the vein. This type of inflammation is called "venitis"; it is localized, limited, and chemical in origin; as distinguished from infective "phlebitis," which is diffuse, of infectious origin, and attacks the deep veins. Embolism does not occur in "venitis," as the clot is aseptic and firmly adherent to the vessel wall, whereas in "phlebitis" the clot may be soft or brittle, and embolism is frequent. The termination of the "venitis" is as follows. The sclerosing fluid irritates the endothelium, which becomes congested and hypertrophied. The fibrin of the blood becomes deposited on the whole length of the irritated and injured endothelium, to which it adheres firmly. The clot becomes organized, sclerosis follows, and the venous cicatricial tissue becomes gradually absorbed in the following weeks. In venitis there is no fever as in phlebitis, because there is no infection; no oedema, because the superficial veins, and not the deep ones, are alone obliterated; and there are no continuous severe pains as in phlebitis, because the vessels of the nerves (the vasa nervorum) are not affected by the salicylate solution. It happens very occasionally that, owing to ulceration, an infective venitis—that is, of a superficial vein—is found; but even in this condition embolism is extremely rare, practically never occurring unless the deep veins are infected. Sicard and Gally proved radiographically (by means of lipiodol in the vein) that the blood flow in varicose veins is reversed, therefore even if embolism does occur it is not dangerous, as the embolus would be carried towards the periphery and not centrally. No case of embolism has occurred at the Hôpital Necker in over three hundred thousand injections, and in my own experience, including the treatment of haemorrhoids with sclerosing injections in many hundreds of cases, I have never had a single case of embolism. Dr. Bensaude of the Hôpital St. Antoine, Paris, the best known French authority on the use of sclerosing injections for the treatment of haemorrhoids, assured me that in the thousands of cases he has treated embolism had never occurred.

Painful Effects of Injection and their Causes.—When the injection has been properly given there are only two possible painful effects, the one immediate—that is, the cramp previously mentioned, a vasomotor phenomenon always temporary, quite bearable, and without danger—the other, more remote and not common, "perivenitis," which is never serious, and indeed when it occurs causes a more rapid and certain cure. Whilst perivenitis persists the part looks red and is tender and warm to touch, but there is no temperature and the patient need not lie up unless symptoms are excessively painful, which is rare. When ulceration occurs following injection it is due to the solution entering the perivenous tissues through faulty technique as follows: (*a*) Injecting fluid outside the vein; (*b*) rupture of the vein from employment of a too strong solution and especially an excessive quantity of a strong solution, and (*c*) injecting small veins too rapidly, causing rupture; (*d*) lack of asepsis. In several hundred cases in whose treatment I assisted at the Hôpital Necker and in my own practice I have not seen one instance of ulcer due to injection of sodium salicylate. As success depends mainly on skilful technique, sclerosing injections, either for haemorrhoids or varicose veins of the limb, should only be given when experience in rectal and intravenous work has been acquired.

6. *After-effects and Possible Complications.*

(*a*) Perivenitis, just mentioned, is the only important after-effect; it usually lasts a few days, rarely longer than a week, and no special treatment or bandage is necessary. In the rare cases where reaction is excessive, rest, local applications, and a supporting bandage are advisable. It must be understood that I am only speaking of the effects of sodium salicylate. With some other solutions marked and very painful perivenitis is not uncommon, and in these cases the treatment ceases to be ambulatory. All varices are not equally affected by injection. The single sinuous vein will frequently yield to even a weak sclerosing solution, and disappears rapidly with no after-effects such as pain or discomfort. In these days of short dresses this type of vein, by protruding through the thin stocking, causes much disfigurement. For this reason more women than men, from "mobiles de coquetterie," as Sicard says, present themselves for treatment, men as a rule only seeking advice when they suffer from voluminous varices which cause much discomfort and hinder them working. The after-effects are naturally more marked in the latter type of case. (*b*) A pigmented brownish line which marks accurately the course of the obliterated vein may persist for a long time; it is due to the destruction of the sympathetic in the sclerosed vein.

Complications of varicose veins such as eczema, ulcer, and haemorrhage, are not contraindications, but are themselves benefited by injections; in the case of ulceration local treatment should be employed in addition to the injections, which latter should be given in the healthy area away from the ulcer. The veins diminish in calibre from the day of injection, and the patient rapidly loses the feeling of heaviness in the limbs of which he previously complained, and all that can be felt (not seen, because the vein does not protrude under the skin after the first injection) is a hard cylindrical zone slightly painful to touch. The patient need not lie up after injection, but can carry on his work and social duties as usual.

Recurrence does not take place in veins which have been completely sclerosed, but occasionally sclerosis is incomplete (especially if the injection has been made perivenously as for haemorrhoids) and the central lumen persists. Fresh injections into the thickened vein will be necessary. New varices sometimes appear a few months after treatment. These readily yield to further injections.

When the sclerosing treatment is finished, general treatment should be instituted in most cases to maintain and prolong the effects of the local treatment. This general treatment should be directed towards the cause of the varices. Sicard and Gaugier are of opinion that varix (excluding that due to pressure and infection) is endocrine in origin—a special hormone circulating in the blood and acting on the sympathetic which regulates the calibre of the vein. When the internal secretion of the endocrine glands is defective or vitiated, varicosity results in their opinion the genital glands (testicles and ovaries) and hypophysis

cerebri are those chiefly concerned, and a course of treatment with extracts of these glands is suggested. Violent exercise, excessive standing, and constipation should be avoided and attention to general hygiene counselled.

The technical details in the foregoing paragraphs are written with the approval of Professor Sicard and Dr. Gaugier, to whom I again express my thanks and indebtedness for enabling me to place them before their British confreres.

A NEW METHOD OF TREATMENT OF LEPROTIC INFECTION OF THE NASAL MUCOSA.

BY

F. G. ROSE, M.D., D.M.R. AND E.CAMB.,

MEDICAL SUPERINTENDENT, MAHAICA LEPER HOSPITAL, FORMERLY GOVERNMENT BACTERIOLOGIST AND PATHOLOGIST, BRITISH GUIANA.

THOUGH in leprosy the nasal mucous membrane is no longer held to be a common site of the primary lesion, it nevertheless remains true that, particularly in cases of the so-called systemic type, the nose, either internally or externally, is a region of very great importance with regard both to frequency of involvement and persistence of infection. In pure nerve leprosy, however, nasal lesions are not common, and indeed probably all supposed nerve cases which show infection of the nasal mucous membrane should be considered to belong to the systemic type.

External lesions of the nose show features no different from those of lesions of the skin covering other parts of the face. Internally the nasal mucous membrane may be the seat of a generalized infiltration of the whole mucosa or localized infiltrations of the septal mucosa, which, when they ulcerate, as sometimes happens, are very difficult to treat. The lesion may spread to the cartilage of the septum, leading to perforation or to complete destruction, or it may extend to the skin at the margins of the alae nasi, forming a creeping ulceration, which gradually erodes the skin and underlying tissues. Probably in some cases the accessory sinuses become involved, and in many, generally advanced, cases it spreads backwards with infiltration and ulceration of the nasopharyngeal and laryngeal mucous membrane. A few early cases of the systemic type have been seen in which the first visible lesion was in the skin of the nose. In these the nasal mucous membrane, at first uninfected, later became involved, apparently by direct extension from the skin.

The affected mucous membrane is never insensitive, sometimes it is highly sensitive, and the ulcers which occasionally form tend to become encrusted and to remain so for long periods. The removal of these crusts causes haemorrhage, which may be severe, and one never fails to find numbers of bacilli beneath. If, when taking a swab, the crust is not removed, the smear may be negative. Wade and Solis[1] have stressed the importance of examining the nasal mucous membrane of the "negative" leper. In this country great emphasis has been laid on such examination, probably too great, for cases bacteriologically negative are not segregated and are *ipso facto* deprived of treatment, which is carried out only at the Leper Hospital. These cases at length swell the ranks of the mutilated victims, who still form a large proportion of our segregated lepers. Our experience here is that some 70 per cent. of cases of the systemic type and some 20 per cent. of cases of the nerve type show infection of the nasal mucous membrane before treatment.

Of late years we have been fortunate in obtaining a number of early cases where nodular infiltration has barely commenced, or at any rate is by no means widespread. In these cases, where nasal infection exists, it tends to persist after the nodules have disappeared. Moreover, in many cases, particularly of the nerve type, this persistence may postpone for some time the conditional discharge of the patient. From these considerations the importance is obvious of a line of treatment which will sterilize the nasal mucous membrane in a few months.

Technique of Treatment.

Ionization appears to bring about the required result. At first we used a 1 per cent. solution of sodium salts prepared in this laboratory by saponification from "*hydnocreol*," which is pure creosoted hydnocarpus oil supplied under this trade name by Messrs. Smith, Stanistreet and Co., Calcutta. Afterwards we used alepol, potassium iodide, and sodium chloride in 1 per cent. solution. The ionization current was obtained either from a galvanic battery or from the main through one of the galvanosets manufactured by the Medical Supply Association, London. Nasal electrodes were improvised from the ordinary small "button" electrodes, wrapped in absorbent wool which had been immersed for a short time in the solution to be used. One electrode was placed in each nostril, pushed well up and kept in position by means of bandages or rubber bands. The patient was told to breathe through the mouth, and a current, whose amperage (usually 20 to 30 ma.) was limited by his capacity of endurance, passed for twenty to thirty minutes.

Type of Cases Treated.

The patients treated may be divided into three groups. (1) Thirteen cases of both systemic and nerve types who had received the usual general and specific treatment for periods varying from nine months to two years, with disappearance of all signs save infection of the nasal mucous membrane. (2) Ten cases, all of the systemic type, under treatment for similar periods, but still showing other signs of activity besides intranasal infection. (3) Two cases of the systemic type before commencing treatment. All these patients were examined once weekly, the whole surface of the nasal mucous membrane being swabbed on both sides to the point of abrasion. The whole slide was examined before being returned as negative or as showing very few bacilli. Five controls, including representatives of the first two groups, were similarly examined week by week.

Results of Treatment.

No lessening of the number of bacilli is apparent until about ten to fourteen days after treatment. Bacilli may disappear after one or two sessions, but frequently there is a relapse, and at least three sessions, generally more, at fortnightly intervals, appear to be necessary for permanent cure. The treatment is somewhat unpleasant, but is readily borne, even by small children, and patients say that nasal breathing is much freer after the treatment. About two weeks after the last of three or more sessions, often after only one or two, the bacilli either disappear or become fewer in number and hard to find on the slide. Later there comes a stage when negative results alternate with positive, a stage which, as the Culion workers have pointed out, often precedes the permanent stage in cases improving under general treatment.

Thirteen of the twenty-five cases treated have been returned at least once as negative, some eight times in succession, though only six had at any time since their admission given a negative result, and then in each case on a single occasion.

Nineteen of the twenty-five have either become negative or show such a reduction in the numbers of bacilli that they have become very hard to find. In the other six cases, all of long standing, it is possible that the sinuses had become involved. The controls showed no such reduction or extreme variability in the results of nasal examination.

It is impossible at present to say whether the cure is permanent, for only two months have elapsed since the conclusion of treatment in many of the cases, but owing to the impending absence of the writer on long leave it was thought desirable to publish these results at once, with a view to confirmation by others who may wish to try the method.

Summary.

Ionization of the nasal mucous membrane with a 1 per cent. solution of certain drugs, especially alepol, produces in many cases an apparently complete cure of leprotic lesions in this site.

It is particularly effective in otherwise negative cases where infection of the nasal mucosa persists, but even cases which have not yet undergone other treatment react.

The ulcers heal and nasal breathing becomes freer after treatment.

Some of the cases have been consistently negative for two months, which is the longest period that had elapsed between the conclusion of treatment and the writing of this paper.

If these results are confirmed it is clear that in a large number of cases the duration of segregation may be considerably curtailed.

THE COMBINATION OF ANILINE DYES AND RADIATION IN THE TREATMENT OF TUMOURS.

BY

J. C. MOTTRAM, M.B.LOND., D.P.H.CANTAB.

(From the Research Laboratories, Radium Institute, London.)

ANILINE dyes have been widely used in attempts to cure cancer in the human subject, and various claims have been made. Recently Mr. Frank Coke has been using preparations of the fluorescein series. The best results were obtained with sodium fluorescein, and he is of opinion that better results are obtained by a combination of this drug and hard *x* rays, than with *x* rays alone. The fluorescein was administered by local external application and by the mouth. Mr. Coke suggested to me that possibly some specific fluorescent action might be taking place. The following experiments have, therefore, been carried out to test this idea.

A slow-growing rat sarcoma was used. Small pieces, approximately 1 c.mm., were exposed to gamma radiation from two radium applicators of 110 mg. $RaBr_2.4H_2O$, having an area of 2 by 2 cm. It was found that whereas three hours' exposure *in vitro* killed the tumour cells, exposure for two and a half hours resulted in no more than delayed growth, when inoculated into rats, as shown in Table I.

TABLE I.—*Growth of Slow Sarcoma after Two and a Half Hours' Exposure to Gamma Radiation in vitro.*

	Days after inoculation—								
	5	7	10	12	14	17	19	21	24
Rat 1	5×4	6×5	8×6	10×6	13×8	16×11	18×12	22×16	25×20
Rat 2	3×3	5×4	7×5	11×6	14×7	15×9	19×10	21×13	24×15
Rat 3	0	3×3	5×5	6×6	9×8	12×10	15×10	15×15	23×18
Rat 4	0	0	0	6×4	7×5	8×6	11×7	15×11	21×12
Rat 5	4×4	5×5	6×5	7×6	8×7	10×9	13×12	14×14	19×15
Rat 6	3×3	4×4	4×4	5×5	6×6	7×6	9×7	17×3	17×12
Rat 7	0	0	0	0	5×5	8×6	11×7	10×7	15×9
Rat 8	0	5×5	6×5	11×6	9×8	10×9	12×11	12×12	15×15
Rat 9	4×4	5×4	5×4	5×5	6×5	7×5	8×5	8×7	10×10
Rat 10	0	0	0	0	0	0	6×6	6×6	11×8

In each of the tables the figures represent the size of the tumours in millimetres. 0=Small nodule not measurable.

Small pieces were likewise exposed to various concentrations of fluorescein in Locke's solution, and it was found that 1/80 per cent. solution applied for six hours had no decided effect on the rate of growth of the tumours resulting from the inoculations (Table II).

TABLE II.—*Growth of Slow Sarcoma.*

	Days after inoculation—											
	5		7		10		12		14		17	
	C	E	C	E	C	E	C	E	C	E	C	E
Rat 1	0	0	6×5	9×5	10×6	14×6	14×8	20×8	16×10	24×14	19×14	33×18
Rat 2	3×5	0	9×5	6×5	12×7	10×6	14×8	12×7				
Rat 3	0	0	0	0	4×4	8×4	7×5	10×6	10×10	14×11	18×11	20×12

C=Control. E=After six hours' treatment with 1/80 per cent. fluorescein.

To test whether the combination of the two agents exhibited any specific effect, exposures of two and a half hours to gamma radiation, and of five hours to 1/200 per cent. fluorescein, were used. The exposures were made in the following manner:

A. Eighteen pieces for two and a half hours in 1/200 per cent. fluorescein, Locke's solution. Then for two and a half hours in 1/200 per cent. fluorescein, Locke's solution, and exposed to gamma radiation at the same time. Then for two and a half hours in Locke's solution, after washing in Locke's solution to remove the dye.

B. Eighteen pieces for two and a half hours in Locke's solution and exposed to gamma radiation at the same time. Then for five hours in 1/200 per cent. fluorescein, Locke's solution.

C. Eighteen pieces, control, for seven and a half hours in Locke's solution.

A and B, therefore, had precisely the same exposures to gamma radiation and to fluorescein; the only difference was that in A the radiation was applied *after* fluorescein treatment, and in B *before* fluorescein treatment.

The fifty-four pieces of tumour were inoculated into nine rats, six pieces into each rat, and the resulting tumours are shown in Table III. There it is seen that the two

L. Ts.=Large tumours. The animals were killed on the seventeenth day.

agents have summated their deleterious action on the tumour cells; alone, neither two and a half hours' gamma radiation nor five hours' fluorescein would have prevented the pieces from growing into tumours.

In A only five tumours resulted from eighteen inoculations, and in B only four tumours. Further, there is no evidence of any specific action; whether the radiation was applied before or after the fluorescein made no difference.

In a previous paper[1] it was shown that the intravenous inoculation of lead colloid into mice bearing tumours and the simultaneous irradiation of the tumour caused their disappearance with doses of these agents, which *alone*

would not produce this result. Here also there was summation, but no evidence of any specific action.

These results, in which more than one agent is brought to bear on a pathological condition, at any rate suggest that the summated action of several agents may be a better form of treatment than the pushing of a single agent to near the limit of the patient's tolerance.

"DEBILITY" IN CHILDREN AND CYCLICAL VOMITING.*

BY

A. A. OSMAN, M.R.C.P.LOND.,

PHYSICIAN, QUEEN MARY'S HOSPITAL, STRATFORD, E.; SENIOR MEDICAL ASSISTANT, GUY'S HOSPITAL.

ALL physicians are familiar with the large group of children who are brought for advice regarding the most varied symptoms, for which no adequate cause can be found, and yet which do not seem to be directly due to some antecedent illness such as scarlet fever, measles, or tonsillitis. Such children are for the most part labelled "debility," and are either given tonics or sent away to the country or seaside, the unlucky ones having their tonsils removed first. It is this group which forms the bulk of all the cases attending any out-patient department for diseases of children.

The object of the present communication is to show that, although the symptoms for which these children attend are varied, yet the common underlying set of causes are of the same nature as those found in the cyclical vomiting of children; in other words, that the "debility" and cyclical vomiting to be described hereafter may be regarded as the minor and major manifestations of one disorder, bearing to each other much the same relation as petit mal and grand mal in epilepsy. Further, it is desired to emphasize the frequency with which cyclical vomiting occurs in children of all classes, and not only among the well-to-do, as is commonly taught. Finally, it is hoped to show that both the minor and the major forms of this disorder are easily preventable by the same treatment.

In September, 1923, a group of 30 children suffering from attacks of cyclical vomiting was collected, observed, treated, and followed up for the following three years. It was then believed that this disorder was rare in children of the hospital class, but it soon became evident that this was not the case. On two separate occasions a census of such cases was taken in the out-patient departments of two London hospitals, and it was found that approximately 30 per cent. of all children over 2 years of age gave a history of typical attacks. Since then it has become apparent that cyclical vomiting in children of the social class that makes use of hospital out-patient departments is so frequent that it is regarded by the parents as a normal accompaniment of childhood. They regard it as a "bilious attack" attributable to indiscretions of diet, and do not as a rule consider it sufficiently important to require medical attention. Probably for these reasons, and because attacks rarely occur in children already in institutions, it has been regarded by the profession as an infrequent condition in hospital class children.

Early in the investigation an attempt was made to study the conditions in the blood and urine before, during, and after the attacks. At first several cases were admitted to hospital, but in none of them did attacks supervene. It therefore became obvious that in-patient observations of this disorder were impracticable, and the cases under observation attended as out-patients at fortnightly intervals. After some months it was noticed that, though new cases of cyclical vomiting were seen, none of those already under observation had further attacks, though no special treatment had been undertaken. In order to secure regular attendance malt extract had been given to all the cases as a placebo; but on further investigation it was found that it was the malt which was preventing the occurrence of attacks, and that sugar in other forms had a similar result. Thereafter all children with this complaint were given extra sugar as a routine, with the result that in the great majority of over 200 cases treated the attacks have been entirely prevented.

It is now well known that the whole subject of cyclical vomiting is intimately related to that of ketosis. Frew[1] in 1911 showed that acetonuria was present in 61.2 per cent. of 662 children admitted to hospital for various reasons. It was first shown by Marfan[2] that attacks of cyclical vomiting were regularly accompanied by excess of ketone bodies in the urine. Gamble, Ross, and Tisdall[3] state that the amount of acidosis present (reduction of serum bicarbonate of blood) is fully accounted for by the excess of ketone bodies in the blood. Ross and Josephs in 1924[4] produced attacks of cyclical vomiting in children by starvation, and from a study of the blood sugar under these conditions suggested that hypoglycaemia was probably an essential feature of the attacks. Brown and Graham[5] in 1926 also studied the blood sugar, plasma bicarbonate, and ketone bodies in the blood and urine of children given a ketogenic (high fat and low carbohydrate) and an antiketogenic (high carbohydrate and low fat) diet, and also the effects of treating the resulting ketosis with sugar, alkalis, and alkalis *plus* sugar. They concluded that sugar was the most useful method of treatment. Investigations on the children forming the subject of this paper show that, at least in many cases, there is not a progressive fall of blood sugar culminating in an attack. On the contrary, the blood sugar often remains normal right up to and during the early stages of the attack, though later it may fall quite suddenly to a very low figure, though not necessarily with any increase in the symptoms present. These facts, together with the knowledge that the prophylactic administration of sugar usually prevents attacks, suggests that the underlying defect is a too rapid depletion of the glycogen reserves of the liver in the circumstances existing at the time. To understand how this glycogen depletion is brought about it will first be necessary to consider the symptomatology of the condition, and then the predisposing and exciting causes.

The cardinal signs and symptoms of cyclical vomiting are extraordinarily constant. They are lassitude, drowsiness, headache, pyrexia, vomiting, and marked muscular prostration. Abdominal pain is frequently complained of, even before vomiting sets in, and constipation is generally present, though diarrhoea accompanies the vomiting in some cases. Pyrexia is invariably present at the outset, and often reaches 103° F. on the first day. In the complete absence of pyrexia cyclical vomiting is unlikely to be the correct diagnosis. The muscular prostration may be extreme, with transient squints, loss of knee-jerks, and carination of the abdomen. In such a case drowsiness may give place to actual coma, and not infrequently there is a mild jaundice with pale-coloured stools. The urine is as a rule acid, scanty, high-coloured, and contains an excess of acetone bodies. Often the attacks are preceded by a prodromal stage lasting from a few hours to a day, with lassitude, anorexia, and headache. Sometimes a sense of chilliness or actual shivering precedes the attack. The vomiting is persistent, and is brought on by the mere sight of food. The vomited material is usually acid, and is often highly coloured with bile. The attacks generally last two or three days and then gradually and spontaneously remit, leaving the child after a few days in normal health. Attacks usually begin at about 3 or 4 years of age, and continue at regular or irregular intervals until 12 or 13 years of age, when they tend to become less frequent and less severe, and by the time of puberty they have generally ceased altogether. Sometimes at puberty the attacks are replaced by symptoms of migraine. In some instances cyclical vomiting commences in infancy, though usually in an atypical form.

It is well recognized that cyclical vomiting only occurs in children with an inherited or acquired nervous instability. On examining the causes which excite the actual attacks it is found that they fall into three main groups, of which the first is by far the most important. They are: (1) mental excitement, such as occurs when attending parties, during examinations, and so forth; (2) infection accompanied by

* Part of this work was carried out with the aid of a grant from the Medical Research Council.

pyrexia, as at the onset of scarlet fever, tonsillitis, and "colds"; (3) muscular over-exertion, as after vigorous games in which there is a competitive element. Hilliger[6] has suggested that all these causes act by the over-production of adrenaline through sympathetic stimulation. The signs and symptoms, the nature of the predisposing and exciting causes, and the readiness with which the attacks can be prevented by the addition of extra sugar to the diet, can all be satisfactorily explained by such an hypothesis. It is common knowledge that most healthy children prefer sugar and "sweets" and dislike fats. This may be readily understood when it is remembered that the child always works on the "all-out" principle, while the adult, with greater cerebral inhibition, has learnt to conserve energy by the highly co-ordinated use of a few muscle groups. The child's need for relatively larger supplies of a readily combustible and assimilable food such as sugar is therefore much greater. The monosaccharides and disaccharides are necessary for sudden demands when glycogen stores are getting low. There can be no doubt that the child's desire for sugar and "sweets" subserves a valuable physiological function, and should be gratified.

Treatment.

The amount of sugar to be given varies in every case and in different circumstances. Thus a child who remains free from attacks on a certain allowance of sugar will require an extra supply before attending a party, or going for a ride, or being subjected to any other stimulus known to cause attacks. The following rules have been successful in a large number of cases, and may be of value as a rough guide. Apparently one form of sugar is as effective as another. At least two level teaspoonfuls of sugar are given in a cup of weak tea for breakfast and tea. For dinner, lemonade sweetened with sugar is given. Sandwiches of bread-and-butter and Demerara sugar are taken at each meal, and in some cases an extra sandwich for supper. Milk is allowed in the tea, and in milk puddings, but is not recommended as a beverage, though if desired it may be taken after being skimmed. Glucose powder, 2 or 3 drachms, is given in lemonade three times a day between meals, or, when this is not possible, the child is allowed and even encouraged to eat sweets (boiled sweets are excellent) instead. The extra glass of milk often provided in the mornings is forbidden, and often the school authorities are informed that the child should be allowed to eat sweets in school. As a result of such measures no untoward results have been encountered at any time during the past five years. Glycosuria has never been found in any of these patients. Occasionally during the first fortnight of such a diet urticaria has been complained of, but without exception it has proved quite transitory, and cleared up without any modification of the treatment. Giving sugar and sweets between meals does not impair the appetite in the majority of cases.

"Debility" and Sugar Shortage.

The term "debility" covers that large group of children who, though not suffering from any recognizable disease, are nevertheless persistently or temporarily in a subnormal state of health. They may seek advice for headache, constipation, listlessness, anaemia (pallor), backwardness, incipient tuberculosis, failure to put on weight, loss of appetite, growing pains, pyrexia, recurrent diarrhoea or colitis, "nervousness," night terrors, nocturnal enuresis, asthma, and cough. This group of symptoms, when not obviously associated with or due to some definite and well-recognized disease, occurs almost exclusively in highly strung nervous children. Acetone bodies are frequently found in the urine of many of these children. Their plasma bicarbonate is subject to much wider variations from the normal than that of children with a stable nervous system, and many of them suffer from persistent acidosis (deceased plasma bicarbonate), of which the exact cause has not yet been determined. The blood sugar, on the average, is not lower than in normal children, and is again subject to greater fluctuations. The conclusion appears to be justified that this great group of children, commonly called debilitated, is really suffering from relative or absolute insufficiency of sugar—that, in fact, it is suffering from a minor form of the disorder called cyclical vomiting. It is not suggested that the symptoms named are necessarily due to shortage of sugar. That they are frequently due to such shortage, however, is shown by the fact that very often they can be cured and prevented by the simple expedient of adding sugar to the diet. Broadly speaking, these minor symptoms are more frequently the manifestations of sugar shortage in younger children; as age increases the symptoms tend to become aggregated into definite major attacks with normal health in the intervening periods. At a later age, again, the major attacks become less frequent, and less severe, and ultimately cease altogether. The predisposing nervous instability may persist throughout life, but during the adult period increased cerebral inhibition exerts some measure of control over the biochemical responses to outside influence. In this connexion it is significant that with increasing age fluctuations in the amounts of many of the normal chemical constituents of the blood become progressively less marked.

Some Common Symptoms.

A detailed consideration of a few common symptoms may serve to illustrate some of the points already made, and perhaps throw some light on the nature of certain complaints frequently met with in paediatric practice.

Sugar shortage, in the sense already considered, would appear to be by far the most common cause of headache and constipation in children, both symptoms, in the majority of cases, yielding readily to extra allowances of sugar. The constipation is probably only an expression of defective tone of the intestinal musculature.

Abdominal pain, with and without obvious constipation, often clears up with sugar treatment. Major attacks of cyclical vomiting are also generally accompanied by abdominal pain, often in the right iliac fossa, and occasionally with tenderness and rigidity. Not infrequently children are seen who have undergone appendicectomy for such symptoms, but with attacks persisting until prophylactic treatment with sugar is instituted. In many cases the differential diagnosis between recurrent appendicitis and cyclical vomiting is quite impossible. Sometimes sugar given by the mouth, or as a 5 per cent. solution of glucose per rectum, produces such rapid amelioration of symptoms as to render postponement of operation reasonably safe. In recurrent cases of abdominal pain simulating appendicitis extra sugar in the diet should always be tried before resorting to operation. The point is of great importance, because the child subject to cyclical vomiting is especially liable to delayed chloroform poisoning.

The common symptoms of early tuberculous infection in children are lassitude, failure to put on weight, pallor, and anorexia. Large numbers of children are diagnosed as tuberculous on these criteria and without evidence of any local lesion. A considerable number of these children never develop active tuberculosis, and not infrequently all the symptoms subside when extra sugar is given.

"Growing pains" are commonly regarded as having a rheumatic origin, or as indicating a predisposition to acute rheumatism. But in many instances these pains may be due to abnormal stresses resulting from the faulty attitudes adopted by children with poor muscle tone. Quite often these pains disappear when the muscle tone is improved by means of an increased allowance of sugar. "Growing pains," it would appear, are more often related to poor muscle tone than to acute or subacute rheumatism, though this view is contrary to that of Goodhart and Still.

The only other single symptom which calls for detailed discussion is unexplained continued pyrexia. Quite commonly children retain a considerable degree of pyrexia, often without other symptoms, long after the apparent subsidence of an acute illness. Sugar treatment may be followed by an immediate and permanent return of normal temperature. The pyrexia in these cases may represent a continued variety of the pyrexia of shorter duration which invariably accompanies major attacks of cyclical vomiting. More than one child has been confined to bed for several months at a time for this reason alone. The following case will illustrate this point.

A boy, aged 7, was admitted to hospital on July 27th, 1927, for unexplained pyrexia, possibly due to tuberculosis. It was not known for how long pyrexia had been present, but it was discovered three weeks previously by his doctor. There was a history

of lassitude, headaches, and constipation for about two months. There was no family history of tuberculosis, and no signs or symptoms of this disease could be discovered in the child. A radiograph of the lungs showed nothing abnormal. He had never suffered from "bilious attacks," and was an only child. As will be seen from the accompanying chart, the temperature became

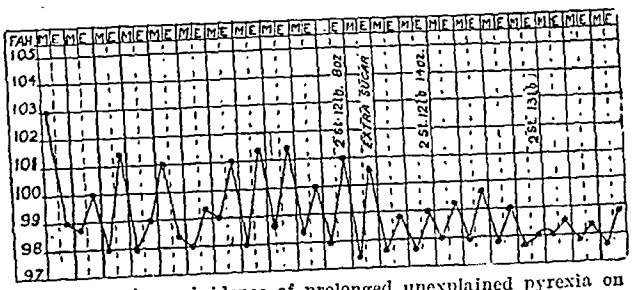

Chart showing subsidence of prolonged unexplained pyrexia on administration of sugar.

normal almost immediately after giving extra sugar (3 drachms of glucose powder in lemonade three times a day). It will be seen also that he at once began to gain in weight. Since then he has attended as an out-patient at intervals, and now (October, 1928) he is apparently in normal health, having had no further symptoms. During the whole of this period he has continued to take glucose.

The following conclusions would appear to be justified.

1. Cyclical vomiting is an extremely common affection in children of all classes.

2. It is due to depletion of the glycogen reserves of the liver.

3. It occurs mainly in "nervous" children, attacks usually being precipitated by mental stress.

4. It can generally be prevented by giving extra sugar in the diet.

5. The child's desire for sweets subserves a physiological function, and should be gratified.

6. A large proportion of cases of "debility" is due also to sugar shortage.

7. Such debility can generally be cured and prevented by increasing the allowance of sugar in the diet.

8. Sugar shortage is the most common cause of headaches, constipation, abdominal pains, and "growing pains" in children.

POSTSCRIPT.

Since writing the above I have read a paper on "The pre-rheumatic child," by Professor C. W. Vining of Leeds (Bath Conference on Rheumatic Disorders, 1928). In it he shows that a very large proportion of frankly rheumatic children give a preceding history of various symptoms of minor ill health, lasting for months or years. He groups these symptoms under the heading of "toxic debility," and shows that their incidence is very much less in normal children. This state of "toxic debility," Professor Vining suggests, is intimately and causally related to the incidence of acute rheumatic fever, and he concludes that "the success of our efforts to prevent and control rheumatism (acute) will be in proportion to the amount of recognition we give to the pre-rheumatic health defect, and I would suggest on the evidence brought forward in this paper that prevention lies first and foremost in the provision of a well-balanced diet from infancy onwards." The symptoms Professor Vining includes under the title of the "pre-rheumatic" state are identical with those I have suggested as being due to a relative insufficiency of sugar in the diet. As, moreover, they may be readily cured and prevented in the majority of cases by the addition of sugar to the diet, it is possible that this dietetic modification affords a means of preventing acute rheumatism, or at least of diminishing its frequency.

SUDDEN DEATH FROM PNEUMONIA WITHOUT APPARENT SYMPTOMS.

BY

JAMES A. STEPHEN, M.B., D.P.H.,

CHILD WELFARE MEDICAL OFFICER, ABERDEEN;

AND

EDWARD R. C. WALKER, M.B., M.R.C.P.ED.

SUDDEN deaths in marasmic infants in the first year of life are not uncommon, especially in the presence of severe anhydraemia. Heart failure, respiratory failure, or what appears to be a sort of general nervous collapse, sometimes brought on by an unsuitable meal, may extinguish suddenly the flickering little life. When the child seems to be doing well and death occurs without any warning symptoms the matter becomes very puzzling. Such deaths are commonly certified as being due to "marasmus," a term which is inadequate, if not actually inaccurate. The following case of this nature, therefore, seems to us of some importance and interest.

A female infant, born on November 13th, 1927, was admitted to the Burnside Infant Welfare Home, Aberdeen, on December 1st, 1927, weighing 6 lb. 9 oz. She was put on the routine feed for infants of her age—namely, lactic acid milk sweetened with dextri-maltose—but did not gain weight satisfactorily. Little could be made out clinically, except that after a few weeks a pustular eruption developed on the chin. This cleared up fairly readily with a coal-tar and zinc paste. There was no albuminuria. Progress, however, remained unsatisfactory, the gain being only 26 ounces in fifteen weeks. At this point one unit of insulin daily was given subcutaneously, followed by a drachm of glucose by the mouth, a method of treatment which has given some happy results in our hands. In the first week of this treatment the child gained 11 ounces, and in the next 3 ounces, and in every way appeared to be much improved. At 2.20 a.m. on March 25th she was found in her cot just dying. During the week prior to death the temperature, taken morning and evening, varied between 97° and 98.2° F., the pulse between 124 and 130, and the respirations between 22 and 28. The 10 p.m. feed on March 24th was finished as usual; at 1.45 a.m. on March 25th her napkins were changed, and there was no suspicion that anything was amiss. The last dose of insulin was given at 3 p.m. the previous day, nearly twelve hours before death.

At the *post-mortem* examination the lower lobes of both lungs were found to be solid and in the red hepatization stage of lobar pneumonia, microscopical sections showing the alveoli to be filled with red cells and leucocytes. A pure culture of pneumococci was grown from the affected lung substance. In the upper lobes were found scattered patches of broncho-pneumonia. The only other abnormality was a large thymus. The thyroid did not appear to be abnormal in any way. Unfortunately, these glands were not weighed.

Discussion.

The point of immediate interest in connexion with this case is that a sudden, unexpected, and apparently inexplicable death in an infant in the first year of life may be due to pneumonia. Dr. Simonds, in Abt's *Pediatrics* (vol. 8, p. 630), indeed, states that broncho-pneumonia is the most common cause of sudden death in the first year of life. Lobar pneumonia is not mentioned in this connexion. While lobar pneumonia is much less frequent in children under 1 year, and is held by some not to occur at all, our experience, confirmed by clinical, radiological, bacteriological, and pathological findings, is that it does occur, and in the case here recorded the pathological and bacteriological findings were as stated above. Discussing the mechanism of death in these cases, Simonds considers that the fatal result is brought about by toxic absorption from the focus, and, probably chiefly, by asphyxia induced by the great reduction in alveoli, which are small in infancy, available for blood exchange. In our case, if asphyxia were the chief cause of death, it would be necessary to postulate its very sudden onset, for it is difficult to see how a child with any degree of respiratory embarrassment could, without showing some recognizable signs of distress, take a feed of several ounces as this child did four hours before death, at which time the pneumonia must almost certainly have been fairly well established. An overwhelming toxaemia seems to be the more probable explanation. In reviewing the case from birth to necropsy four points stand out—namely, (*a*) the failure to gain weight normally on an adequate diet, arguing a faulty metabolism; (*b*) increase in weight in response to insulin;

(*c*) complete lack of resistance to infection, to the extent of failure to produce symptoms; and (*d*) the presence of a large thymus gland. The sequence of cause and effect may have been as follows. An innate weakness was present of endocrine outfit in particular, probably of thyroid, pituitary, and adrenals, indicated by the response to insulin, which we believe exerts its beneficial effect indirectly through stimulation of pituitary and thyroid; and possibly also by the presence of a large thymus. On account of this deficiency metabolism was faulty and gain in weight was unsatisfactory. Stimulation of the so-called "katabolic" glands by insulin brought about increased metabolic activity with consequent gain in weight. A pneumococcal infection occurred, and the endocrines, probably innately deficient, or perhaps weakened by stimulation, failed along with the autonomic nervous system to respond with defensive activity and consequent production of symptoms, and death occurred. This explanation is in line with that suggested by Ramsay in his interesting paper on "The resistance factor in disease" in the *Journal* of April 14th, 1928 (p. 628).

If this interpretation be approximately true, then it seems possible that another class of case may be rescued from that limbo of infantile diagnosis termed variously "marasmus," "wasting," "debility," and "atrepsia"; and, if this be a correct conception of the pathology of these cases, therapeusis based on it should hold out hopes of their more successful treatment. The rational procedure would appear to be to supplement the deficient glands by giving reliable glandular extracts, and concurrently, or probably later, to stimulate them by some such method as insulin injections.

Summary.

A case of sudden death in an infant of 4 months, from pneumonia which produced no symptoms, is reported. It is suggested that these cases are commoner than is supposed, and also that the underlying pathology is concerned with an innately deficient endocrine system. Treatment based on the latter supposition is proposed.

SPREADING SUBCUTANEOUS EMPHYSEMA AFTER FRACTURE OF RIB.

THE following case is of special interest since it illustrates an effective treatment of spreading subcutaneous emphysema following the fracture of a rib; two instances of this condition were recently published in the *British Medical Journal* by Mr. J. A. C. Macewen (November 17th, 1928, p. 892). The patient in the present case left the wards of the Albert Dock Hospital towards the end of December.

A dock labourer, aged 54, was admitted on October 5th, 1923, after having fallen 15 feet into the hold of a ship, together with a heavy wooden hatch, which fell across his chest. There was fracture of the seventh left rib in the posterior axillary line, with a small patch of emphysema over the site of fracture. On the succeeding days the emphysema spread rapidly as follows: October 5th: A circular patch about 6 inches in diameter. October 6th: Left scapular and both pectoral regions. October 8th: Left axilla and upper arm, left supraclavicular fossa. October 9th, 10 a.m.: Chest wall emphysematous throughout, with spread to the left side of the abdominal wall, the left arm down to the wrist, and the right arm down to the elbow. 6 p.m.: Emphysema covered both arms to the wrists, the entire surface of the body, and both legs to the knees. There was a sudden spread to the neck and face, up to the supraorbital ridges; the whole face was now uniformly spherical with the eyelids ballooned and standing out from the general level, giving an appearance not unlike that of two golf-balls on the surface of a football. 7 p.m.: "Eggshell" crackling could be felt in the finger-tips and nail beds, and respiration was becoming so seriously embarrassed that tracheotomy was contemplated. Acting on a suggestion by Mr. T. Pomfret Kilner, surgeon to the hospital, pleural puncture by a medium-sized trocar and cannula was performed on the affected side, permitting free ingress and egress of air, with partial collapse of the lung.

The theory advanced for this treatment was that the continuous increase of emphysema was due to escape of air by way of the pleural cavity into the subcutaneous tissues under pressure; if, then air were allowed to pass freely out of the pleural space this pressure would cease to operate.

There was no further spread of the emphysema, and after twelve hours the cannula was removed, respiration being less embarrassed. Recovery was uneventful, the emphysema passing off in the reverse order of its appearance; on October 25th there was none present.

It would appear from this experience that so simple an expedient as pleural puncture at an opportune moment would avert the necessity for the accepted treatment by multiple incisions in situations where the subcutaneous tissues are distended.

Albert Dock Hospital, London, E. ROBERT V. GOODLIFFE, M.R.C.S., L.R.C.P.

AN UNUSUAL CASE OF HYPERKERATOSIS BLENNORRHAGICA.

CERTAIN uncommon characteristics would seem to render this case of hyperkeratosis blennorrhagica worthy of record.

A patient contracted [illegible] in August, 1924; he was ill for seven days, and had [illegible]. He was reinfected in December, 1927; there [illegible], and he was discharged cured after forty days' treatment. He was readmitted to the Royal Naval Hospital, Haslar, with gonorrhoea on March 1st, 1928; there were no complications, and he was discharged cured on April 9th.

The patient was readmitted to the Royal Naval Hospital, Haslar, on August 24th with well-marked hyperkeratosis blennorrhagica of both feet only. He stated that two months prior to admission to hospital he noticed dried skin appearing in different places, first on the right heel, secondly on the left heel, then spreading over the soles and toes, and becoming gradually more painful on pressure, especially while standing on guard. He finally was put on light duty on account of inability to perform his work.

It is stated by most authorities that the following three symptoms constitute the syndrome: gonorrhoeal urethritis, gonococcal arthritis, and hyperkeratosis. The point of interest is that the above patient has never had any form of joint trouble whatsoever since his first infection with the gonococcus in 1924, and no joint trouble has been present up to the time of his discharge "cured" from hospital on September 26th. Secondly, the patient had not noticed any urethral discharge prior to readmission to hospital on August 24th, and none has been present since.

Examination of a urethral smear after prostatic massage on August 27th, 1928, revealed a few Gram-positive organisms, together with an occasional pus and epithelial cell. Urine cultures on August 28th and September 11th were sterile, and a urethral smear on September 10th was negative. A urethroscope examination was negative, and the prostate was normal. The patient was a fit, healthy man in every other respect.

We have had four cases of hyperkeratosis in this hospital during the last two years: three patients had urethritis, and arthritis in conjunction.

In the present case hyperkeratosis was the only symptom, and probably the infection of March, 1928, could be held responsible for this. The point of interest is that if such a disease as gonorrhoeal iritis can occur ten years or more after initial infection, and appear as the only metastatic exhibition, is it not possible that hyperkeratosis may appear as the sole manifestation also?

The treatment applied was purely local—namely, alkaline foot baths and nikalgin ointment.

T. R. LLOYD JONES, Surgeon Commander, R.N.
Royal Naval Hospital, Haslar.

INJECTION TREATMENT OF VARICOSE VEINS.

I RECENTLY had a difficult case of varicose veins to deal with, and the satisfactory sequel to a change of procedure may justify its publication.

The internal saphenous was very bad, with nine large nodules from the internal condyle upwards, the lower leg being like a fisherman's net with veins of varying sizes. I began with a 0.5 c.cm. dose quinine urethane, and for the space of five weeks increased the dose until I gave three 1 c.cm. injections at the one sitting. The first injections were given at the upper end of the vein, and the later ones at the lower, all were given slowly and cautiously, and none had any effect. I decided, therefore, to adopt different tactics.

I thoroughly prepared the nodule at the internal condyle, emptied it, and kept it empty by digital pressure. I then partially dilated it by injecting forcibly 2.5 c.cm. of quinine urethane. This was kept in the nodule for thirty seconds and then the leg was lowered for thirty seconds, the patient standing on it; after this the leg was elevated for one minute, and then the patient was instructed to walk about. The result was sclerosis of the meshwork on the leg and of the nodule with two inches of the vein above it and of one other nodule. A week later I gave a similar injection half-way up the thigh, and after another week had elapsed found no further injection necessary.

The reasons for bringing this case to notice are the large single dose employed; the forceful injection, and finally, the injection in the middle of the vein, which ensured that either centrifugal or centripetal flow would be of equal advantage.

Bentecula, South Uist.

LARGE URETHRAL CALCULUS.

THE following case is of so unusual a nature that it is deemed worthy of being placed on record.

A joiner, aged 54, was admitted to the Royal Infirmary, Glasgow, in June, 1928, complaining of the presence of a hard mass in the scrotum, and inability to pass urine per urethram. He stated that he first had difficulty in passing urine five years previously, and that he then had frequency also, necessitating his getting up during the night to pass water. Then a painful swelling developed at the base of the penis, which ultimately discharged urine. Many similar swellings developed subsequently. He denied gonorrhoea, and the Wassermann reaction was negative.

On examination eleven sinuses were found on the scrotum, two of which were discharging pus, and one urine. Condylomatous-like masses were present around the anus, one of which was discharging pus. Lying under the scrotum, in the middle line, a large, hard, irregular mass was felt, fixed to the deeper tissues of the perineum, but not to the pelvis. The inguinal glands were palpable on both sides. The patient had a right inguinal hernia. The urethra was found to be quite impermeable beyond the penile portion. A vertical incision was therefore made in the middle line of the scrotum down on to the hard mass, which was found to consist of a stone, chiefly phosphatic, occupying the dilated urethra, immediately proximal to the complete obliteration met by bougies when examining. The stone weighed 45 grams, and measured 5.25 by 3.5 cm. Beyond the stone the urethra was fully permeable up to the bladder.

Cultures taken from the pus yielded coliform organisms, Gram-positive cocci, and diphtheroid bacilli, but no gonococci.

The patient made an uneventful and satisfactory recovery.

J. MACEWEN,
Surgeon, Royal Infirmary, Glasgow.

ERYTHEMA NODOSUM.

IT may be of interest, following the review of the monograph by Dr. Odery Symes in the *British Medical Journal* of December 29th, 1928 (p. 1180), to report three cases of erythema nodosum which have occurred at this institution during the last two months. It would lead one to suspect that there may be an infective element present in the production of the disease. The two cases of definite erythema nodosum appeared in a class of eighteen patients who were kept apart from the other 1,200 cases in the institution. One nurse, who is in attendance on this special class, has also been under treatment during the last two months for the disease.

The first patient, an idiot girl, aged 13, had an attack of erythema nodosum in May, 1927, which lasted six weeks; node-like swellings were present on both legs. The lesions started on the left leg and later attacked the right one; finally the thighs, buttocks, and arms were affected. The girl has just recovered from another attack which started on November 3rd, 1928; one large patch about the size of a pigeon's egg was present on the extensor aspect of the left leg. The attack was milder and of shorter duration than the former one.

An imbecile boy, aged 11, who had signs suggesting tuberculosis of the lungs, complained of pains in his legs, and was sent to bed on December 18th, 1928, suffering from erythema nodosum. The lesions were first observed in the right leg, and the nodal swellings appeared later on the left one; no indurated areas were visible on the arms or scapular regions.

A nurse, aged 20, complained of pain and aching in the legs, arms, and back on December 18th, 1928; she also had malaise, and there was a tendency to constipation. The indurated patches were first seen on the thighs and buttocks as reddish spots; they later spread to her legs and arms. The attack was acute but of short duration, and she was able to get up on December 25th.

Reports of Societies.

POST-OPERATIVE THROMBOSIS.

ON January 18th, with Dr. J. S. FAIRBAIRN in the chair, the Sections of Pathology, Surgery, and Obstetrics of the Royal Society of Medicine combined for a discussion on "Post-operative thrombosis."

Dr. W. HOWEL EVANS discussed the changes in the blood after operation, and in other conditions associated with thrombosis and embolism, in particular parturition, fractures of bones, and acute generalized infections such as pneumonia. Such changes in the blood were only one aspect of a many-sided problem. He devoted himself principally to the question of blood platelets, and gave a series of fifty cases of surgical operations, minor and major, in most of which the platelet count before operation was within normal limits, and, following operation, rose to a maximum by the tenth day, returning to normal within another ten days. The rise began to be marked after an interval of four to six days. The average increase for the whole series was 60 per cent., but while a number—chiefly the trivial cases—showed little or no rise, the major cases showed sometimes a rise of 100 to 150 per cent. A similar sequence was observed after parturition, but in five cases in which Caesarean section was done the platelets began to rise more quickly, and showed an average increase of 200 per cent. During the febrile period of pneumonia the platelets were usually diminished, but following the crisis they began to rise. The platelet reaction appeared, from control observations, to be independent of mere loss of blood, or of confinement to bed, or of anaesthesia, or sepsis. The only apparent common factor of the demonstrated blood changes was tissue injury and the absorption of breakdown products. Such injury was inseparable from surgical procedures, and the blood changes might be regarded as a physiological response.

Mr. D. H. PATEY said that four manifestations of post-operative thrombosis were met with—namely, localized thrombosis, massive pulmonary embolism, minor pulmonary embolism, and latent thrombosis. The first two types were most easily studied, as they were the most readily diagnosed. In considering thrombokinase absorption theories, he described experiments reproducing conditions of tissue juice absorption, which might be presumed to take place in man after operation, and as all these experiments were negative he concluded that this type of theory could not be supported on experimental facts at present. He discussed the role of anatomical and pathological variations in the veins, and in passing said that certain investigations of his own went to negative the idea that the sitting-up position after operation was a factor in the production of post-operative thrombosis by causing kinking and possibly traumatism of the femoral vein. Dr. Howel Evans's work on platelets was a definite advance towards knowledge of the subject, though to establish the theory firmly collateral evidence was required—first, unequivocal proof that splenectomy (following which the platelet rise was most marked) was specially liable to be followed by thrombosis, and secondly, experimental verification. The stasis aspect of the question offered at present the most hopeful side for attack. Measures directed towards the tone of the abdominal wall were much more likely to be successful than efforts to induce movement of an inhibited diaphragm.

Mr. VICTOR BONNEY dealt with three theories of the process. In favour of the bacterial theory was the fact that thrombosis which was obvious either by the clot being palpable or by visible signs of venous blockage was always preceded by fever and local pain. Cases of pulmonary embolism did not usually exhibit these symptoms prior to embolism, though pain and fever occurred afterwards. Embolism was rare when there was prior evidence of thrombosis, suggesting that clots due to, or accompanied by, definite signs of phlebitis were too firmly anchored in the vein to shift easily. Thrombosis, if bacterial, bore no relation, however, to the degree of sepsis in the operation area, being commoner after "clean" operations, such as hysterectomy and shortening of round ligaments, than after operations on pyosalpinx or suppurative appendicitis. The second or toxic theory was unlikely, because there was no knowledge of any toxaemic conditions whose lesions exhibited anomalous distribution; thrombosis was always limited to veins of the lower half of the body, chiefly the legs, and usually the left leg. Toxaemic lesions were generalized. The third theory was that of a haemic process. Little was known about the conditions of increase of the clotting power of blood, but in haemophilia, in which the reverse was the case, lesions were generalized. The balance of evidence was in favour of a bacterial process, but there were difficulties. Thrombosis was far commoner after operations involving the peritoneal cavity, and this was against the theory of a septicaemic lesion, since septicaemia was no more common after operations on the peritoneal cavity than after operations elsewhere. Thrombosis was rare after operations to the uterus via the vagina, seeming to suggest that trauma to the uterus was not a sufficient cause unless there was also trauma to the peritoneum, but against this deduction was post-parturitional

thrombosis. The preference for the left leg pointed to the lesion being due to local infection, but left leg thrombosis occurred after right-sided operations, so that the route of infection was probably not through veins or lymphatics connecting directly with the leg. The period at which symptoms appeared—from the tenth day onwards—was significant; in ordinary infections symptoms appeared in two or three days. Therefore the organism probably did not belong to the group of ordinary septic organisms, whose incubation period was short. It was possible that post-operative thrombosis was due to anaerobic spore infection from the patient's own bowel. *B. coli* appeared in urine after all abdominal sections; organisms, coming from the bowel, found entrance to the urinary tract via the kidney, and probably across the peritoneal cavity. If so, the peritoneal cavity contained free organisms, and these, after operation, might enter the leg by lymphatic conduction. The anatomical relations of the parts on the left side might favour such transmission more than on the right. This would explain why the peritoneal cavity was so often a factor in the sequence leading up to thrombosis, and why the left side was more frequently affected. Such a suggestion, however, failed to explain leg thrombosis after operations on parts like the breast and vagina.

Mr. J. P. LOCKHART-MUMMERY said that this problem was entirely a physiological one, and would never be solved until a great deal more was understood about intravascular clotting. Post-operative thrombosis was far commoner after abdominal operations than after any other kind of operation, and this was due to interference with the abdominal wall. The common period for the occurrence of the post-operative infarct was about the tenth day. The actual thrombus occurred immediately after operation, but by the tenth day the intravascular clot softened and began to move. Mere stasis of blood within the vein did not cause intravascular clotting. Such clotting also did not occur in normal blood. The factors required were stasis *plus* something else, and what that "something else" was remained doubtful; it might be excessive blood platelets or thrombokinase. To some extent stasis in the vein could be prevented, and this appeared to be the only method available at present for averting post-operative infarct.

Dr. F. J. MCCANN said that in the vast majority of these cases the cause was some error of technique on the part of the surgeon or some mistake in after-treatment. It had been said that something must be done to bring the abdominal wall to the diaphragm. What could be done was to diminish the pain which the patient suffered in the abdominal wall. A stitch tied very tightly caused agony, and had an extraordinary influence on diaphragmatic contraction. If the abdominal wall was stitched carefully and the stitches were brought together without constriction, and if haemorrhage was carefully arrested, the patient should have very little pain indeed. One important error was to tie "chunks of tissue" with thick material. The idea surely should be to pick out the isolated vessels and tie them with thin material. In after-treatment the great point was movement from the first. Patients should be allowed to lie in any position they wished provided they were comfortable. Knee pillows should be thrown away. He let patients get up on the seventh day, before the stitches were removed. The contraction of the muscle promoted healing. As a consequence of these precautions, during the last twenty-five years he had not had a single case of pulmonary embolism, either in his hospital or private practice.

Mr. CECIL ROWNTREE said that all surgeons would congratulate Dr. McCann on the great success which had attended his surgical endeavours, although the points he had mentioned were familiar to most surgeons of experience, and they all endeavoured to follow them. It was true, of course, that thrombosis, when it occurred, usually followed operations, but occasionally it followed normal labour. In his experience pulmonary embolism had always been entirely unexpected. If, therefore, a patient was unfortunate enough to get an obvious femoral thrombosis, he felt quite happy about the case, being sure that pulmonary embolism would not ensue. A possible explanation of the occurrence was a mechanical one. There was a marginal clot, coming from the iliac vein, and "waggling about" in the blood stream, becoming detached at some moment and getting into the pulmonary artery. He mentioned some curious cases, which might have been coincidence, or, on the other hand, might have some significance. For example, in two small hospitals at which he had operated for some years, and in which the conditions, at least so far as he was concerned, were exactly the same, a number of these sequels had occurred at one, and none at all at the other. He was trying to discover what differences there might be in nursing, feeding, and so forth.

In some further discussion Dr. TOM HARE gave an account of the examination of the blood of some lambing ewes, in which the platelets followed much the same course after parturition as Dr. Howel Evans had described in the case of human blood. The increase above the normal count reached 140 per cent. Mr. DAVID LEVI exhibited a substance called "heparin," prepared in America, injection of which into blood was said to stop clotting. Dr. W. CRAMER entered into a discussion on the difference between intravascular clotting and thrombosis. Fibrin, he said, was formed by the blood platelets disintegrating, which was an entirely different process from agglutination. Miss FRANCES IVENS had found thrombosis much more likely to occur in pregnancy toxaemias, where organisms were present in large numbers in the urine.

Dr. HOWEL EVANS, *in reply*, took up the point made by Mr. Patey as to the operation of splenectomy, saying that there was some connexion between splenectomy and thrombosis, though he did not think the whole story was yet forthcoming. He had not brought forward the platelet theory as elucidating the problem, but only as one factor.

EPIPHYSEAL INJURIES OF THE WRIST-JOINT.

At a meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine on January 18th Mr. C. THURSTAN HOLLAND read a *paper on epiphyseal injuries* at the wrist.

Mr. Thurstan Holland commenced with a short reference to the development of the bones at the wrist-joint from the point of view of the ossification of the carpal bones and the epiphyses; he pointed out the importance of accurate knowledge as regards this in considering *radiographs* of this region for the diagnosis of injury. He then commented on the statistics in Poland's book on epiphyseal injuries. A comparison was made between these statistics and those which it was now possible to obtain from *x*-ray examinations; and it was remarked that *x* rays here, as in most other fields of *x*-ray observation, had been revolutionary. Poland's statistics, largely drawn from *post-mortem* examination and what must have been somewhat uncertain clinical diagnoses, were shown to be obviously unreliable as a guide to the relative frequency of different epiphyseal injuries. Following this, an analysis was made of injuries to the lower parts of the radius and ulna within two inches of the wrist-joint, as seen in the *x*-ray department of the Liverpool Children's Hospital over a period of seven years, the age limit being 12 years. The statistics showed quite plainly that a backward displacement of the lower radial epiphysis, simple or complicated by other injuries, was by far the commonest lesion, and that, practically, it took the place in children of the Colles fracture in the adult, being brought about by the same kind of trauma. A true Colles fracture under the age of 12 was very rare: Mr. Holland had seen only one case. After this introduction there followed the main part of the paper—namely, the *x*-ray diagnosis of these injuries and the exact meaning of the *x*-ray appearances. It was concluded that in nearly all, if not in all of the cases in which the epiphysis was displaced, there was also a [illegible] This diaphyseal injury was either [illegible] (1) a flake or bone torn off the [illegible] in the direction of the displace[illegible] bone (described by Werenskiold [illegible] the diaphysis opposite to the [illegible] referred to the paper by Werenskiold [illegible] for disagreeing with some of the [illegible] was shown that technical care [illegible] examination to make sure of [illegible]

injury, but Mr. Holland believed that it did occur in all cases in which the epiphysis was definitely displaced. It became an important *x*-ray point in diagnosis (1) in cases in which only an antero-posterior view had been taken; (2) in those cases in which at the time the *x*-ray picture was taken the epiphysis had either slipped back into its normal position or had been induced by manipulation. If this diaphyseal injury was shown radiographically it could only mean that there had been a displacement of the epiphysis, since it could not occur as an injury by itself.

The paper was illustrated by about thirty radiographs, chosen to demonstrate the various points raised.

THE INJECTION TREATMENT OF VARICOSE VEINS.

AT a meeting of the Forfarshire Medical Association at University College, Dundee, on November 22nd, 1928, with the president, Professor J. A. KYNOCH, in the chair, Mr. JOHN TAYLOR read a paper on the injection treatment of varicose veins.

Mr. Taylor gave first a historical account of the method, and mentioned the various solutions employed; he then went on to consider the kinds of cases suitable for the treatment. In the "hose-pipe" variety the veins were tortuous, with sacculations in the thigh and leg, and involvement of the whole saphenous system; in another variety there were bunches of veins in the leg and commencing affection of the lower thigh. These types were found in both sexes. Another common female type was the parous, where the legs were fat and showed only little venous "pouchings" like strings of beads; and lastly, there was the variety with big saccules. Mr. Taylor said that phlebectasis in the lower limb began in general in the deep veins, and deep varices were more common than superficial. He called attention to the fact that Sir Benjamin Brodie's observation of eighty years ago that the venous flow in the saphenous system was reversed when the valves were incompetent had been confirmed by lipiodol injections and *x*-ray examinations. It followed that an embolus would have a tendency to be directed distally and not upwards towards the saphenous opening. In his own clinic he had frequently been able to demonstrate not only that the flow was directed distally in the valveless saphena, but that in some cases it continued so against gravity when the limb was elevated to an angle of 30 degrees. After injection one of three things might happen. In the ideal case the vein walls adhered at once, with immediate and permanent obliteration of the channel. This reaction occurred in various degrees, the least of which was a condition of gradual thrombosis taking three to four days, but with good functional and cosmetic results. Secondly, there might be an extensive reaction in both directions from the site of puncture, with sudden clotting and the ultimate formation of a fibrous cord which might take months to disappear. Thirdly, there might be no reaction at all, but when the injection was repeated a week later an extensive reaction might follow. With regard to leakage it had to be remembered that contractile power in the wall of the dilated vein was lost to such an extent that there was no chance of immediate and complete sealing of the puncture. The injection was rapidly diluted, and it appeared that the solution passed rapidly into the general circulation, for some of the patients tasted quinine a few moments after the injection. Mr. Taylor described how he tried to empty the veins when injecting; the patient had thus to be in the recumbent position; he had always failed to produce clotting in a normal vein with the usual doses. Further information was required concerning the detailed pathological changes in the intima of varicose veins and the reasons why reactions to equal doses in similar cases were so varied, apart from the rate of dilution and rate of injection. He insisted that the injection treatment of varicose veins was not simply the injection of a sclerosing agent into any varicose vein that came under observation. Bad results were undoubtedly occurring, and it was only by an understanding of the conditions and experience of the method that they could diminish therapeutic errors and prevent this treatment from falling into undeserved disrepute.

ULTRA-VIOLET MICROSCOPY.

AT the annual meeting of the Royal Microscopical Society on January 16th Mr. J. E. BARNARD, F.R.S., delivered his presidential address on the subject of microscopy with the aid of ultra-violet radiations, and gave a full description of the construction and manipulation of the elaborate apparatus necessary for this purpose.

Mr. Barnard mentioned that only three outfits of the kind he described were in existence; one was at the Rockefeller Institute in New York, another was at the Imperial College of Science, and the third was in his own laboratory in the institution of the Medical Research Council at Mill Hill. On one occasion he had transported the outfit for the purpose of demonstration, and it was a week before it could be got back into working order; he had resolved never again to remove it from its bed. The first difficulty in ultra-violet microscopy arose from the comparative scarcity of the materials which could be employed; these had to be natural, for artificial glasses and the like were at present of no real service. The first material was quartz, which could be obtained in the crystalline or the fused state. The crystalline form was variable—it might be coloured or colourless, and frequently disclosed impurities such as iron—but fused quartz was still more difficult to use on account of its lack of homogeneity. Another material, fluorite, might be quite useless owing to its fluorescence. In ultra-violet work the objectives were made from fused quartz, the slide on which the object was placed was crystalline quartz, and the cover glass was of fused quartz again. Mr. Barnard said that it would be better, if one could ensure a sufficiently good quartz, to have the slide of fused quartz also, but the difficulties in the way were considerable; the specimens had to be flawless, free from internal stresses and strains, and only small pieces usually could be found to meet these conditions. Another difficulty in the ultra-violet as compared with ordinary microscopy was the source of illumination. The ordinary worker with the microscope did not need to concern himself much about his source of light so long as it furnished sufficient good illumination, but in ultra-violet work the objective so far had been corrected for only one wave-length. It was necessary to use a spark spectrum, most generally of cadmium, on account of its bright line in the ultra-violet region. If the magnesium or zinc spectrum could be used it would in some ways be better, but the arrangement of the bands was not so convenient. The visible focusing was done with the aid of a mercury vapour lamp. The necessity for visible focusing, said Mr. Barnard, was one of the great embarrassments in dealing with the virus type of organism, which was so quickly destroyed by light. The visible focusing having been accomplished, an ingenious mechanism permitted a change over from the glass objective to the quartz objective without any dislocation or variation in the position of the image. An urgent necessity was an objective of higher numerical aperture than it was possible to work with at present. All the materials with which his work was done were of a watery consistency, the medium in which the objects were immersed having a refractive index of about 1.4. A numerical aperture of 1.35 would be a real help; the aperture used was about 1.20. Mr. Barnard added that the selection of photographic plates furnished another difficulty. The most rapid plates were not necessarily the best for ultra-violet work, and panchromatic plates, containing as they did a dye, usually fluorescent, were unsuitable. He used an ordinary plate, coated with a thin layer of paraffin oil, which caused a certain amount of brightening of the lines in the shorter wave-lengths of the spectrum. Mr. Barnard exhibited a few typical results, beginning with what Dr. Carpenter, the authority on the microscope, had called the "torment of microscope makers and rival diatom resolvers," the *Amphipleura pellucida*: he showed how the striations were clearly brought out under the ultra-violet method, whereas with the ordinary microscope they were scarcely visible. He also demonstrated the great enhancement in the structure of the image as the result of the ultra-violet method in the case of various micro-organisms. The results in many cases were certainly much more revealing than anything obtainable by transmitted light.

Reviews.

SIR WILLIAM HAMER ON EPIDEMIOLOGY.

A book by Sir WILLIAM HAMER on epidemiology is a literary event. His scholarly equipment, wide practical experience, and literary charm long since secured for him a high place upon the roll which includes the names of Creighton, Payne, and Greenhill. The Anglo-French Library of Medical and Biological Science could hardly have secured a contributor from this side of the channel with more of the intellectual finesse which appeals to our neighbours. Those who are already familiar with Sir William Hamer's papers and official reports may be a little disappointed that his book is not rather more of a unity and rather less of a compilation than it actually is. The phrase "as I said in the year so-and-so" is not an encouraging conversational gambit; it suggests a bore. Few men have less of the bore in them than Sir William Hamer, though he *does* quote himself rather often. But the quotations are very good, and will be new to most French and some English readers. Another general criticism is that, although the book is called *Epidemiology, Old and New*,[1] one could easily find a more appropriate title. Perhaps a contemporary of Sir William's hero would have entitled the book: "Of Catarrhal Epidemicks and Such as be infestuous to the Brain and Nervous Stock; whereunto are added an Anatomy of that most excellent Physician, Thomas Sydenham (*medicus in omne aevum nobilis*), and divers Animadversions glancing at the Schismaticks vulgarly known as Bacteriologists."

A reader who wishes to understand what is, in the reviewer's opinion, Sir William Hamer's principal contribution to knowledge should begin a first reading on page 52 and read straight on to page 102. He should then pass to page 131 and read the next twenty pages, studying the rest of the book afterwards. The sections cited exhibit the historical setting, as Sir George Newman called it, of epidemic influenzas, old and new, in a most attractive and instructive way. Nobody else, save perhaps Creighton or Dr. Crookshank, could have written those pages at all, and nobody else has so clearly illustrated the idea of a *sequence* of epidemic happenings, so well shown that the historical succession of "diseases" is something more than "a tale told by an idiot, full of sound and fury," and does signify something. This is a considerable achievement, more than enough to justify the existence of the book. If, therefore, the remainder of this notice is critical, that is not because the reviewer is blind to Sir William Hamer's great merits, or presumes to put himself upon an equal footing with so learned an epidemiologist. Still, to be quite candid, one feels that Sir William's sparkling manner often covers essentially confused ideas: that, for instance, much of the gospel according to St. Thomas is mythology, and would have moved that eminent physician Dr. Thomas Sydenham, in spite of his austerity, to hearty laughter. As an example one may take Sir William Hamer's reaction to Freind's criticism of his hero. Freind made the point that although Sydenham *said* the fevers, particularly the continued fevers, of his different constitutions were essentially different and needed different *treatment*, he did in fact treat them all in the same way, and reference to the fourth chapter of Book I, the third of Book III, and the second of Book V of the *Obs. Med.*, where the treatments of the continued fevers of 1661–64, 1667–69, and 1673–75 are laid down, seems to bear out Freind's remark. If there is a difference it has escaped both the reviewer and Sir William Hamer. For this is the way Sir William meets the criticism. He observes that the criticism gives expression to *the* difficulty, that which again and again troubled Sydenham himself. He goes on to say that in the dedicatory epistle to the third edition of *Obs. Med.* Sydenham expressly mentioned that his growing experience of fevers had shown him that in thinking, in earlier days, that he could forge "a Delphic sword, in the shape of some *methodus medendi*, which should meet all cases" he had been wrong. This reply is, surely, a classical example of *ignoratio elenchi*. The very point of Freind's criticism is that Sydenham's quite dogmatic statement (which Freind quotes) about the fevers of different constitutions requiring utterly different treatments is inserted (according to Greenhill) for the first time in the edition of 1676, but Sydenham does *not* give in this latest edition any indication of how he varied his treatment. Since nobody supposes that Sydenham, who was a great physician, would conceal an important rule of practice, Freind, like a sensible man, concluded that Sydenham's speculations about epidemic constitutions did not influence his conduct as a practitioner of medicine. It might perhaps be added that when Sydenham changed his opinion as to the epidemiological nature of the winter fever of 1679—a matter to which Sir William Hamer devotes much praise—he did not change his treatment. His recommendation in the postscript to the tractate on dropsy, when he thought the fever was an intercurrent, is identically the same with his recommendation in the monitory schedule when he had satisfied himself that it was a genuine "stationary fever."

There is, of course, an answer to Freind's criticism, but it is an answer which Sir William Hamer, in the role of hagiologist, is estopped from giving—namely, that in the famous Section 3 of Chapter II, Book I, of the 1676 edition of *Obs. Med.* Sydenham is displaying a confusion of thought. Surely fevers might be epidemiologically distinct and yet clinically identical. Water-borne typhoid and fly-borne typhoid are epidemiologically different, but the clinical treatment of the *patients* might well be the same. One could give many other instances of what seems illogical reasoning—for instance, the whimsical notion that the discovery of ultramicroscopical viruses is, in some mysterious way, a point against bacteriologists—but it would be ungrateful to end upon a discordant note. It may be that Sir William has found more genius and prescience in Thomas Sydenham than were really there, but respect for the mighty dead is not so common an attitude that we can afford to speak lightly of it. *Maxima reverentia*, no doubt, *debetur pueris*. But it will do the *pueri* no harm to see that a man who has played a great part in the sanitary administration of London of the twentieth century loves and reverences as his master a London practitioner of medicine who actually moved and had his being before even the Medical Department of the Privy Council came into existence.

M. G.

[1] *Epidemiology, Old and New.* By Sir William Hamer, M.D., F.R.C.P. The Anglo-French Library of Medical and Biological Science. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1928. (8½ × 5½, pp. x + 180; illustrated. 9s. net.)

FEVER, CLIMATE, AND HORMONES.

It is a trite observation that the avenues to knowledge are strange and not to be predicted. We ask of Nature a definite question, and how often she answers by asking another! The obstinate inquirer who will not be deflected from his chosen path is dismayed, but happy is he who is content to give experiment its head. *Fever, Heat Regulation, Climate, and the Thyroid-Adrenal Apparatus*[2] is the embracing title of a volume in which Dr. W. CRAMER describes his investigations over many years along paths which may be traced back to an intended inquiry into the problem of cancer. The goal he set up was not attained, but the author's peregrinations were not mere idling. They led him to some definite and quite fascinating conclusions upon the diverse subjects indicated in the title.

Dr. Cramer's thesis may be briefly summarized: "With the exception of respiration, all the factors concerned in the heat regulation of warm-blooded animals are under the direct control of the sympathetic nervous system, and, therefore, subject to control by the functional activity of the thyroid and adrenal glands." The sympathetic system controls heat production through its effects upon metabolism, while it controls heat loss by the opposed effects upon the cutaneous vessels and the sweat glands. It follows that stimulation of the sympathetic by increasing heat production and restricting its dissipation produces a type of fever. It is argued that the stimulation of the thyroid-adrenal apparatus by toxins may be the physiological basis for the fevers of bacterial origin. The argument extends

X RAYS IN UROLOGY.

VOLUME VII of *Annals of Roentgenology*,[5] edited by Dr. JAMES T. CASE, is devoted to the subject of urological roentgenology. The authors are Dr. HUGH YOUNG, clinical professor of urology at the Johns Hopkins University, and Dr. CHARLES WATERS, instructor in clinical roentgenology at the same university. In their preface they call attention to the fact that the great progress made in the last ten years in the diagnosis of urinary conditions is to a very considerable extent due to improvements in methods of *x*-ray examination. Previously *x* rays in urology were limited to the diagnosis of calculi. With the introduction of opaque solutions to delineate the contour of the bladder, renal pelvis, ureters, and urethra, vast new possibilities were opened up. The authors' object in writing the present volume is to interest the radiologist in the multiple problems of the urologist and to supply a large number of *x*-ray photographs, with their clinical histories attached, so that radiologists and urologists alike may have a store on which to draw and with which to compare cases coming under their own care. The opening chapter deals with equipment, and especially with different models of combined *x*-ray and cystoscopic tables. In Chapter II an account is given of the topography, anatomy, and physiology of the urinary tract. The remainder of the work is devoted to abnormalities and pathological conditions of the kidneys, ureters, and bladder. At the beginning of each chapter is a brief summary of the pathology of the conditions dealt with, and this is followed by a number of excellent radiograms illustrating these conditions, together with their case-sheets. By this method both surgeon and *x*-ray expert are able to obtain a more intimate knowledge of each other's problems. It is unnecessary to say that drawing, as the authors do, on the resources of the Johns Hopkins University and of the Brady Urological Institute, there is a wealth of material such as is at the disposition of few other writers. Moreover, no expense has been spared in the reproduction of the radiograms. Although the price that must be charged for such a volume will set a limit to the number of buyers, it will undoubtedly be of the greatest use to all surgeons and radiologists dealing extensively with genito-urinary conditions.

METABOLISM OF TUMOURS.

REFERENCE has already been made in these columns (December 11th, 1926, p. 1124) to Professor WARBURG's work on the metabolism of tumours.[6] A translation of the work has been included in the Nouvelle Collection Scientifique, issued by the Libraire Felix Alcan, with the addition of a chapter in which the author gives a summary of his views on the cancer problem. He considers that there is no specific excitant of cancer, and that, among possible causes, micro-organisms are not in a majority. For him the problem is one of cellular physiology, and he approaches it by attempting to distinguish the characteristics of cancerous as compared with normal metabolism. To this end he has compared the differences exhibited by the two tissues in regard to the functions of fermentation and tissue-respiration. He finds that cancerous tissue exhibits the lactic fermentation, while in ordinary circumstances normal tissues do not. Lactic fermentation, however, becomes manifest in the latter under asphyxial conditions, and it is found that the lactic fermentation of cancerous tissue is about ten times more abundant than in resting normal tissue under asphyxial conditions, but is quantitatively identical with that in normal proliferating (embryonic) tissue under those conditions. The characteristic of

[6] *Metabolisme Cellulaire et Métabolisme des Tumeurs.* Publié par Otto Warburg. Traduits par E. Aubel et L. Genevois. Tome i et Tome ii. Nouvelle Collection ... Paris: F. Alcan. 1928. (Cr. 8vo, Tome i, pp. viii + 233, ... figures; Tome ii, pp. 217, 25 figures. 30 fr. the volume.)

cancerous metabolism, therefore, as regards the two functions in question, is that the tissue-respiration is so far altered that it fails to eliminate the normal ferment action in proliferating cells. Among the agents which have the power of altering the respiration in this elective manner is arsenic, and the following experiments with that agent are cited by Warburg in support of his observations: Carrel treated chicken embryos with arsenic and other poisons, and on injecting them into fowls produced sarcomas; A. Fischer treated a culture of embryo spleen with arsenic, and found that the cells behaved under culture like cancer cells, and on injecting them into fowls produced sarcomas. In both experiments the malignant cells exhibited an intense fermentation. According to Warburg the cause of cancer resides in the anaerobic component of the metabolism of normal cells in process of proliferation, and in the fact that this component is more resistant to lesions than the respiratory component. The proliferative activity of cancer cells thus receives an explanation, but the destructive tendency on the surrounding tissues remains unexplained. Warburg suggests that the lactic acid resulting from the fermentation may perhaps render the tissues more vulnerable.

THE DIAGNOSIS OF SPINAL DISEASE.

THE book of DRS. OUDARD, HESNARD, and COUREAUD, with an introduction by Professor SICARD, on diagnosis in affections of the vertebral column in the adult[7] is highly specialized, for, as its title implies, its 250 pages are devoted to the symptomatology and diagnosis of spinal disease, without any reference to pathology or treatment. The exclusion of disease in children and adolescents narrows the field still more. The authors are officers of the French marine medical service and professors of the naval medical school at Toulon. Professor Sicard of the Necker Hospital in Paris points out that new means of diagnosis have of late years been discovered which to a great extent supersede the tactus eruditus and the experienced eye and mind of the surgeon of past generations. These means are x rays, lumbar and sacral puncture, and analysis of the cerebrospinal fluid, and injection of lipiodol, followed by radiological examinations with screen and plate. The application of these various measures is fully described, and stress is laid on their importance, somewhat to the neglect of methods that have been proved by time. Epidural as well as intrathecal injections are discussed, and the method of carrying them out described, especially the technique of injection into the lower part of the sacral canal, where there is no risk of injuring nerve trunks. Injuries of vertebrae, such as crush fractures, are dismissed very perfunctorily, the authors' chief interest being evidently in inflammatory and infective affections. Spondylitis from various causes, or supposed causes, osteomyelitis, neoplasms, syphilis, and congenital malformations are briefly discussed, and there is a chapter on spondylitis ankylosans or Leri's disease, and on rhizomelic spondylitis or the Strümpell-Marie disease. There is no index to this book, and the defect is not compensated by the table of contents, which is not at all full, and lacking in some page references.

A NEW TRANSLATION OF "DE MOTU CORDIS."

THE tercentenary of the publication of Harvey's *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus* was celebrated in the United States, as in this country, by special commemorative meetings in a number of the chief medical centres—Philadelphia, New York, Baltimore, and Boston—and now a permanent historical milestone has been erected by Dr. CHAUNCEY D. LEAKE, professor of pharmacology in the University of California, in the form of a new translation[8] of the masterpiece in the language and spirit of the present day. The translation, which is preceded by a facsimile of the original (1628) edition, has been suitably but not excessively supplemented by critical footnotes containing references to biographical details and modern physiological knowledge. In a postscript Professor Leake says that, so far as he can find out, his is the third attempt to translate Harvey's classic into English, the other two being an apparently anonymous effort prefaced by Zachariah Wood of Rotterdam and printed in 1653, and Robert Willis's well-known translation in 1847. In Mr. Geoffrey Keynes's *Bibliography of the Writings of William Harvey, M.D.* (which Professor Leake, writing in June, 1928, would not have seen), there is a note of the translation made in 1832–33 by Dr. Michael Ryan, editor of the London *Medical and Surgical Journal*, in which it appeared. Our readers will remember that the 1653 translation was beautifully reproduced by the Nonesuch Press last year; as Mr. Keynes points out, it included "a poem on the death of the author seven years before he died, a grim, if unintentional, jest which Harvey no doubt knew how to appreciate." The present translation was in the first instance made from the miserably printed Longhine edition of 1697, of which the only copy Mr. Keynes could trace is in the library of the College of Physicians of Philadelphia; subsequently Professor Leake was enabled to collate this with a facsimile of the original edition and so to make corrections in his translation. The text is in good English and the reproduction of the illustrations and the general get-up of the volume are correspondingly satisfactory.

NOTES ON BOOKS.

WE reviewed the first edition of *Gould's Medical Dictionary*[9] in its present form in September, 1926. Its popularity and success is vouched for by the fact that it was sold out five months before this edition could be got ready. The 76,000 words of the first edition have been increased in the second to 85,000, and it has 125 more pages. The publishers properly draw attention to the fact that the tables of micro-organisms have been increased in number from seventeen to sixty-eight, into which all the names have been collected. Other additions are a table of operations, a physician's and veterinarian's dosage table, and a diet table. Were we to attempt to go through the 1,522 pages of this volume in search of corrigenda our notice would hardly be ready in time for the appearance of the next edition In reviewing the first we mentioned a few entries which we thought needed amendment. We are flattered to find that nearly all our suggestions have been adopted, though Glisson's sling is still absent and love-sickness is still defined as erotomania, and Houston and Allingham still hold the pride of place denied to Paget and Hutchinson. This is a great dictionary of medical terms, in quality as well as quantity. Whether the time has not come, or is not at least approaching, when the burden of the editor, publisher, and reader should be lightened by jettisoning the most ancient and archaic words in the vessel before its successor is launched, must be a question for careful consideration, as is a like problem in our larger public libraries.

In preparing the second edition of his *Physiotherapy in General Practice*,[10] the first edition of which was reviewed in these columns on November 21st, 1925, Dr. E. BELLIS CLAYTON has taken the opportunity to revise the work as a whole, and to enlarge it by including sections on the uses and administration of ultra-violet radiation, radiant heat, diathermy, and other forms of electrical treatment. The work is intended to guide the doctor in the selection of appropriate physiotherapeutic devices, and the masseuse who will administer them under his direction. Treatment by massage, movements, exercises, heat, light, and electricity are described, and some account is given of the indications for their use in diseases of the various systems. The book is clearly written, and on the whole the descriptions of treatment are sufficiently detailed; but the section on ultra-violet radiation would be improved by the inclusion of some account of the conditions contra-indicating its use. The only contraindication mentioned by the author is tuberculosis.

The seventh edition of Dr. RICHARD SUTTON'S textbook on *Diseases of the Skin*[11] is now before us, and bears convincing testimony to the popularity which it enjoys, more particularly in America. Like other textbooks, it has grown with its subject—to such a size, indeed, that it has been found impossible to contain it within a single volume. Consequently, like other less complicated organisms, it has increased by fission, and there are now two volumes. This is a distinct advantage, and makes the book much easier to handle. Apart from this, all the old excellences and characteristics are maintained. Dr. Sutton and his efficient assistants have brought the present edition well up to date, and we have sought in vain to find some serious omission. The printing, illustrations, and general turn-out are also good.

We have perused a book on *Pharmaceutical and Medical Chemistry*,[12] by SADTLER, COBLENTZ, and HOSTMANN. It contains an introduction to the study of chemistry, and deals chiefly (as the title implies) with drugs and medicaments. It also treats of general chemistry to the usual extent found in books of its kind. This voluminous book contains much information of practical value, some of it presented in a discursive, almost voluble, form, and some of it abrupt, if not fragmentary. The introductory part is not wholly satisfactory; it seems to have been written with more haste to set down facts than to illuminate them. Otherwise the facts are generally adequate for the needs the book is intended to serve, and the volume will be a useful aid in studying the chemistry of drugs.

A somewhat remarkable booklet by Dr. DENIS MULDER, director of the medical *x*-ray institute in Bandoeng (Java), in which the text is in English and in German (each page being divided longitudinally, is entitled *Total X-Fotos*.[13] Essentially it is a plea for long-distance radiography, but the author is not satisfied with the usual three metres used for so-called tele-radiography, and has taken radiographs at distances of from eight to ten metres. Profusely illustrated as it is by *x*-ray photographs of various kinds of things, such as flowers, shells, etc., perhaps the most interesting pictures are those of complete human beings, taken by one exposure on either a single film *plus* intensifying screens, or on a series of films and screens elaborately joined up together. The author is obviously an enthusiast who has spared neither time nor expense, and some of his results are really wonderful, even if not so useful as his enthusiasm leads him to believe. Radiographs of the entire human body—the living body—taken at a distance of ten metres from tube to film, and this without damaging the tube, appear to be unique, and are very interesting.

The Traveller's Pocket Reference[14] to the "XXth Century Health and Pleasure Resorts of Europe" is published by the Anglo-Continental and International Offices, and contains hints to travellers, maps, and information about the chief Continental countries which attract those in search of recreation or better health. It is of a convenient size for the pocket, and includes an up-to-date list of hotels, pensions, schools, and medical establishments. From the same offices also has been received a pamphlet[15] giving an illustrated list of medical and balneological establishments and cure resorts on the Continent.

Among the publications of the Church of England Zenana Missionary Society are stories illustrating medical work in India. *Some Women of Sindh*,[16] by Dr. RUTH WESTERN, describes something of the lives and thoughts of patients admitted into the hospitals at Sukkur and Larkana. Their fatalism is shown by the story of an attempt at general vaccination during a small-pox epidemic. The opinion in the bazaars was: "What is the use of trying to interfere with fate? If it is written that our children will get small-pox, no doubt they will get it; if not, they will escape." A child with convulsions had been treated by the local barber with a strong counter-irritant over a fontanelle. The result was a permanently bald spot; but the parents imputed no blame, for after all "man can only apply treatment, and leave the result to fate." There is pathos in the story of the mother who lost her child through small-pox, and was surprised at the distress of the hospital doctors, who had known the child a long time; she did not expect strangers to care. And the custom by which women have to give the eldest son all that he wants was useful when a small boy insisted on remaining in the hospital, from which his mother wished unwisely to remove him. In Dr. ETHEL BLEAKLEY'S *A Country Doctor in Bengal*[17] the miserable condition of the childless wife or widow in India is emphasized. She attributes many cases of blindness to constant weeping at mournings for the loss of husband and children.

[11] *Diseases of the Skin.* By Richard L. Sutton, M.D., etc. In two volumes. Seventh edition, revised and enlarged. London: H. Kimpton. 1928. (Roy. 8vo, vol. I, pp. 654, 506 figures, 5 plates, vol. II. pp. 740, 731 figures, 6 plates. 52s. 6d. net the two volumes.)

[12] *Pharmaceutical and Medical Chemistry.* By Samuel P. Sadtler, Ph.D., LL.D., V. Coblentz, Ph.D., F.C.S., and Jeannot Hostmann, Ph.G. Sixth edition, revised and rewritten by Freeman P. Stroup, Ph.M. London: J. B. Lippincott Company. (Med. 8vo, pp. xv + 748, 31 figures. 32s. net.)

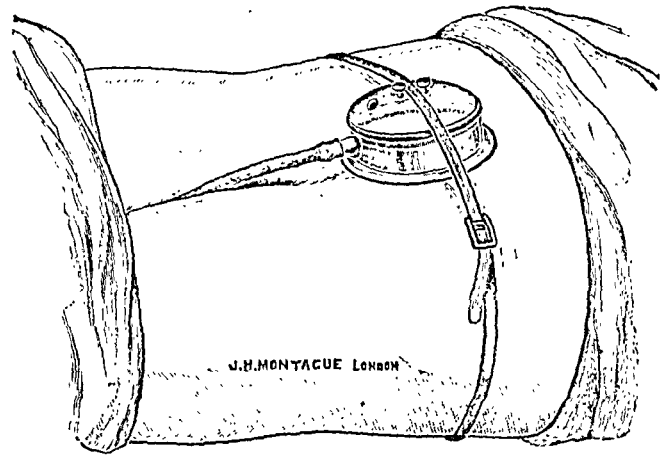
PREPARATIONS AND APPLIANCES.

AN IMPROVED BOX FOR USE AFTER SUPRAPUBIC CYSTOTOMY.

MR. SYDNEY G. MACDONALD, F.R.C.S. (London, W.), writes: The new box is an improvement on the old Hamilton Irving box; this is wrong mechanically, consisting as it does of an oval box which has to adjust itself to a convex or concave surface. To this end it is held by four straps, which can never maintain an equal tension, for with each movement the patient



tightens one at the expense of the rest, thus causing displacement of the box and leakage. The new box consists of a section of a sphere fixed at its top central point (by a single band of half-inch elastic) so that pressure is distributed equally to every part of the rim. Thus with every movement of the patient the sphere of the rim adjusts itself mechanically to the convex (or concave) surface of the abdomen. The boxes are made for me by J. H. Montague, 69, New Bond Street, London, W.

A PORTABLE ELECTRO-CARDIOGRAPH.

A portable electro-cardiograph was shown for the first time by the Cambridge Instrument Company, Ltd. (Grosvenor Place, S.W.), at the recent exhibition of the Physical and Optical Societies at South Kensington. It was claimed for this apparatus that its sensitivity was such that the records were comparable with those of the standard Einthoven galvanometer, over which it had the advantage in compactness and lightness. A novel form of camera, daylight loading, is used for taking films, which are wrapped around the cylindrical holes and exposed in three sections in the ordinary way. The operation of the camera and a small automatic time-marker is effected by depressing and releasing a button switch. The time-marker rules a line on the record at each twenty-fifth of a second, and a heavier line at each fifth.

BELTS AND CORSETS.

We have received from Salt and Son, Limited, of Birmingham, a catalogue of their surgical belts and corsets. This firm is one which does not approach the public direct, but advertises only to the medical profession, and makes surgical appliances to the prescription of the practitioner. A feature of the catalogue is the excellent descriptive illustrations, which are designed to bring out the points on which the makers desire precise information and measurement in the prescriptions forwarded. A large range of supports for abdominal and other conditions is provided.

THE X-RAY DARK-ROOM.

In our review of the trade exhibition at the Cardiff Annual Meeting we drew special attention to the "Metalix" portable *x*-ray apparatus shown by Philips Lamps, Ltd. (Charing Cross Road, W.C.), which was one of the outstanding exhibits. We have now received a pamphlet containing details of the necessary equipment to enable the radiologist using this tube to carry out the development of his own *x*-ray films with the minimum of trouble.

A NEW SALICYLIC ESTER.

We are asked to state that the new salicylic ester—"S.E.D." (Morson)—to which reference was made by Dr. A. Gordon Watson on December 22nd, 1928 (p. 1143), may be had from Messrs. Steele and Marsh, chemists, 6, Milsom Street, Bath.

British Medical Journal.

SATURDAY, JANUARY 26TH, 1929.

MILK AND THE RATE OF GROWTH OF CHILDREN.

ABOUT a year ago there was published in the *British Medical Journal*, and discussed in a leading article, a report on the influence of milk on the rate of growth of school children. This report, which was prepared by Dr. J. B. Orr, chairman of the Research Committee of the Scottish Milk and Health Association, set forth the results of an investigation carried out at the instance of a committee under the chairmanship of Sir Leslie Mackenzie of the Scottish Board of Health, the cost of the inquiry being defrayed by a grant made by the Empire Marketing Board to the Rowett Research Institute, Aberdeen. At the time of issue the preliminary nature of this report was emphasized, since it had been determined to repeat the tests before formulating a definite opinion. Nevertheless, the data emerging appeared to Dr. Orr to warrant a forecast that at the close of the further series of investigations it would be found, when all checks had been applied, that there were adequate grounds for the conclusion that the addition of milk to the dietary of school children leads to a greater rate of growth, as manifested by an increase of height and weight; that this increase is accompanied by an improvement in the general condition of the children; and that separated milk has a high efficiency as a growth-producing food.

A second preliminary report on the subject, made on this occasion, in the absence of Dr. Orr abroad, by Dr. Gerald Leighton, now of the Department of Health for Scotland, contains an account of the further tests which have been employed. The full text, with tables, appeared in our issue of January 5th at page 23. The total number of children investigated was 1,425. The centres at which the tests were made were Peterhead, Aberdeen, Dundee, Edinburgh, Glasgow, Greenock, and Belfast; the ages of the subjects were 13 to 14, 9 to 10, and 6 to 7. At each centre the children were placed in four groups, of which the first received whole milk, the second separated milk, and the third a biscuit ration of the caloric value of the separated milk. The fourth group had no addition to its diet, and acted as a control. The daily milk ration was one pint for the ages 13 to 14 and 9 to 10, and three-quarters of a pint for the age 6 to 7. At two of the centres the whole milk was certified, and at the remainder pasteurized. The separated milk was machine-skimmed. The period of the inquiry was from November, 1927, to June, 1928. Milk samples were tested at the Rowett Research Institute. The average fat content of the whole milk was 3.85 per cent., of the separated milk 0.33 per cent. At all age groups jointly the milk-rationed children—taking the whole-milk and the separated-milk groups together—increased in height by an average of 1.4585 inches, and the non-milk-rationed children by an average of 1.1810 inches, giving a difference in favour of the milk-rationed children of 0.2775 inch. The milk-rationed children increased in weight by an average of 3.5776 lb., and the non-milk-rationed by an average of 2.4610 lb., a difference in favour of the milk-rationed children of 1.1166 lb. These differences in the average increase of height and weight brought out by the further tests were more in favour of the milk-rationed children than the corresponding differences of the earlier report, which were 0.258 inch and 0.643 lb., mainly, it would appear, on account of the fact that in the earlier report the average increase of height and weight of the non-milk-rationed were relatively larger. It seems rather a pity that in the report percentages have been introduced with the view of interpreting these differences; they may convey to the mind of the casual reader an exaggerated impression of the magnitude of the quantities. Contrasting the four dietetic groups with one another under the three age periods it is seen that in every case the milk-rationed children are ahead of the biscuit-rationed and the controls. The greatest increase of height was found in the 6 to 7 year milk-rationed group. The greatest increase of weight was in the 13 to 14 year separated-milk group.

An outstanding feature of the second preliminary report is the test carried out in order to ascertain the effect of reversing the position of certain groups of the earlier inquiry. The following examples indicate the method and the results obtained. A group of 5 to 6 year children, who in 1927 received separated milk, with an average height increase of 1.500 inch and an average weight increase of 2.407 lb., were put on biscuits in 1928. Their height increase fell to 1.351 inch and their weight increase to 2.212 lb. Another group of 5 to 6 year children, who in 1927 had biscuits, with an average height increase of 1.101 inch and an average weight increase of 2.234 lb., were put on separated milk in 1928. Their height increase rose to 1 454 inch and their weight increase to 2.237 lb. In addition to changes for the better, like the above, which can be measured and weighed, the milk-rationed children improved in condition. The report states that they acquired a sleek appearance, that their hair was glossy, their nails were smooth, and their spirits high. Teachers and janitors found them more difficult to manage than the biscuit-fed and the control cases; this agrees with the observation in the leading article of a year ago that the aggressive races of the world have usually been milk consumers.

The second report bears out the forecast made in its predecessor, strengthening the claims of milk to be accounted a primary factor in the nutrition and growth of children. Much administrative effort is focused to-day on producing a cleaner milk; the problem of securing a more copious use of milk, especially by children, is of even greater importance. The clean milk movement is self-commended and merits cordial support, but it is no disparagement to suggest that more disease may be occasioned by the lack of milk than by the consumption of milk that is lacking in cleanliness.

AMERICAN IDEALS IN MEDICAL EDUCATION.

IN North America, where last year no fewer than 11,000 individuals tried to become medical students, the keen interest in medical education took practical form in the establishment in 1925 of a carefully chosen commission on this subject, under the chairmanship of President A. Lawrence Lowell of Harvard. The Commission issued its first report in 1927, of which a notice appeared in the *Journal* of May 28th, 1927 (p. 979), and it now provides, free of charge to those interested in these educational problems, a third but not final report.[1] This deals with the three divisions of pre-medical education, the teaching of the medical sciences (physics, chemistry, biology, human anatomy,

[1] *Third Report of the Commission on Medical Education.* Pp. 75. October, 1928. Office, 215, Whitney Avenue, New Haven, Conn.

and physiology), and clinical training, for each of which a special committee was appointed. The report is divided into two parts, and has several appendixes. In the first part the principles underlying these various branches are set out, and in the second part each subject is further discussed and amplified; in order to save time and repetition the two parts will be briefly considered together.

With the changing opinion attendant on progress and investigation of the problem, medical education is in America rapidly becoming recognized as one of the most important forms of higher education, and not an isolated problem of professional training. Further, the conception of the right line of general education is to encourage independent thought, individuality, and self-development. As even with a four-years college course a student may find it difficult to satisfy the specific requirements of the best medical schools, and at the same time to secure a good general education, it is important that the medical schools should not require from the entrants more than a grounding in the fundamentals of physics, chemistry, and biology. The instruction in these basic sciences provided in the college courses is not, however, always that best adapted for the future medical student. Much of the inorganic chemistry thus has commercial applications, a large part of organic chemistry is concerned with dyes and similar industries, physics is closely connected with engineering, and biology is not specially taught in its relation to the human organism. The laboratory work is regarded by the Commission as excessive, being too much directed to manipulative training at the expense of general principles. Mathematics and the rudiments of psychology are becoming more essential parts of the pre-medical instruction. Emphasis is laid on the axiom that though clinical medicine may not be a science, the basic sciences form not only its foundation but its scaffolding, and again and again the Commission urges the importance of allowing and encouraging students to think for themselves so as to acquire the intellectual equipment necessary for their future independent professional life. Sir Squire Sprigge, in his account of a recent visit to representative medical teaching centres in America, notes "how great a stress is laid in the United States upon the amount of time the student spends upon the various subjects of study, a stress that is entailed by the absence of a general system of examinations as we understand examinations in this country."[2]

The teaching in human anatomy, biochemistry, and physiology is criticized as being too much occupied, in the early stages, with a mass of detail, much of which, the Commission suggests, might be postponed until the student is engaged on neurology, orthopaedics, or other special clinical branches. This change would both shorten the period of preliminary scientific study and help to correlate the scientific and clinical subjects. With regard to this correlation between scientific and clinical instruction, the point is made that this should not be carried to the extent of "spoon-feeding," as one of the most important features in his training is that the student should work out many of these correlations for himself. The essential teaching in pathology, a subject on the borderland between the medical sciences and clinical instruction, is usually correlated with practical medicine by clinico-pathological conferences, and is becoming more experimental as distinguished from purely structural.

Clinical training begins by an extension of the scientific course, and the student should have free time to return to the basic sciences and expand his knowledge of them at the points where they bear directly on clinical problems. The changing character of medical practice in North America cannot be disregarded when considering the most suitable arrangement of the clinical training. We confess to some surprise in hearing that as many as 40 per cent. of recent graduates specialize, half of these without any experience at all of general practice; it is therefore highly desirable that a broad, comprehensive education and a resident appointment should be provided. More than once in the course of this report the Commission insists that the unit of medical and clinical study is the patient and not the disease, and that the student should accordingly gain an insight into the social, psychological, economic, and other aspects of human life and its environment. It is satisfactory to gather that the generally accepted opinion favours post-graduate training for specialists. Like Sir George Newman, the Commission considers that the ideal of preventive medicine should permeate teaching during the whole period of clinical instruction; but at present ordinary medical teachers, even if they are alive to this duty, are scarcely fitted to undertake it, and until this is altered there seems small prospect of instilling into the student's mind the much-needed general idea that prevention is a real and daily duty of the practitioner of medicine.

This report shows the deep and thoughtful interest taken in the difficult problems of medical education by the medical teachers of the United States. Among the points most prominently brought out are the Commissioners' anxiety to avoid the mass production of standardized medical men and women, and the stress they lay on securing individual treatment for all medical students and encouraging their self-development in every way possible.

[2] Lancet, Supplement, January 5th, 1929.

PARATYPHOID BACILLI IN SEWAGE.

THE task of tracking down the source of infection in an epidemic of intestinal disease may perhaps be simplified in the future. Dr. Allan Gray, whose paper appears at p. 142, has shown that it is possible for the bacteriologist to isolate paratyphoid bacilli from sewage, and has succeeded in proving the presence of these bacteria in some tributary sewers and their absence in others. He has not carried his investigations far enough to discover the source of the pathogenic germs, but probably they were derived from a carrier in a locality from which the sewer drained. In the event of an outbreak of paratyphoid fever in a large community with a water-carriage system of sewage disposal it might be possible to localize the source of the infection by systematic bacteriological examination of the leading sewers and their tributaries. Of course, in considering the significance of the paratyphoid-enteritidis group of bacilli, disease of animals as well as of man must be kept in mind. In this large and not very clearly defined group of bacilli there are some which cause disease in man only, others in animals only, and some in both man and animals. There are, however, refinements in bacteriological technique which allow these different types to be distinguished in most cases. There is nothing surprising in the announcement that paratyphoid bacilli are present in sewage, since it is likely that a carrier or two of paratyphoid lurks in every community. What is surprising is that Dr. Gray should have succeeded in separating out the pathogenic germs from the host of non-pathogenic. This achievement points to a useful advance in bacteriological technique, but unfortunately Dr. Gray does not give us sufficient information to decide which is the most profitable method to adopt in the search

for paratyphoid bacilli. His results seem to have been rather inconsistent, perhaps owing to the irregular distribution of paratyphoid bacilli in the material he was studying. It is to be hoped that if he pursues his investigations and gains a larger experience he will be able to give more definite guidance on this point. The presence of typhoid and paratyphoid bacilli in the underground currents of sewage need not cause any such uneasiness as did the recent gas explosions in the underground subways of Holborn. No danger is threatened by these germs provided the sewers are watertight and the sewage disposed of without risking contamination of the water supply. Pathogenic bacteria quickly disappear from sewage. Adapted to a different climate and diet, they quickly drop out of the race when competing with the hardy microscopic population of the sewage farm.

ELECTROCUTION FROM ULTRA-VIOLET RAY LAMP.

A CASE is reported in which a young man was found dead in a bath, with an ultra-violet ray lamp beside him. Death was attributed to shock, and an electrical expert, who examined the lamp at the request of the coroner, gave evidence to the effect that there were five ways in which an electric shock might have been sustained from the apparatus. The deceased had purchased the lamp in order to treat himself for blackheads on the back of the neck, and the makers had supplied a book of instructions. About this book the coroner remarked that it appeared to be a "puff," suggesting that the apparatus would cure every disease that mortal flesh is heir to, and that it gave no adequate warning of the dangers which might attend the use of the lamp when connected to a house current of 230 volts. It was stated that the lamp was of faulty construction, and that the insulating material used in it was very inefficient. In commenting lately on a case of electrocution in the *x*-ray room (December 29th, 1928, p. 1186), we suggested that the time had come when some further legislative action might be taken to ensure that electrical apparatus offered for sale should conform to a certain standard of safety, such is now exacted in the case of many other articles—for example, the cylinders used in storing compressed gases. Nearly all electro-medical apparatus is protected by patent, and it should not be difficult, when specifications are submitted for the granting of a patent, to have these examined with reference to the safety of the proposed device. Another question raised by this unfortunate accident is whether there should not be some kind of control over the sale to the general public of such a dangerous appliance as an ultra-violet ray lamp. We have frequently pointed out the dangers which may follow improper use of these rays. It must be remembered that the mercury vapour lamp produces rays which are absent from the solar spectrum, and to which, therefore, the human body is unaccustomed; these rays have been shown to have a powerful action in setting up chemical changes in the body cells; the nature of these changes has not yet been fully investigated. Sunlight at sea-level contains less than 2 per cent. of ultra-violet light, whereas the Kromayer lamp emits nearly 50 per cent. of such radiation. It is therefore very misleading to assert, as do the makers of some lamps on the market, that such lamps supply sunlight; they emit, as a matter of fact, a different kind of radiation, the effects of which may be very different from those following exposure to the sun. The experience of many workers in the past few years has established ultra-violet radiation as a valuable therapeutic agent; but, like most other methods of treatment, it has its definite indications and contraindications, and its effects depend largely on the technique employed. The subject is much too complicated to be adequately compressed into a booklet given away with every machine sold, or to be understood without special knowledge both of medicine and of electricity. There is, indeed, grave danger of serious harm being done, and a useful method of treatment brought into disrepute, if it is carried out otherwise than under the supervision of persons properly qualified to administer it. In a recent case in France a masseur was prosecuted and fined heavily for giving ultra-violet ray treatment, the court taking the view that he was not qualified to do so except under medical supervision. The French Council of Public Hygiene has declared that such treatment should be given only in hospital services and by specialist physicians, while in the United States the Council of Physical Therapy has drawn attention to the danger of the promiscuous sale of ultra-violet ray lamps to the general public. At the last Annual Meeting of the British Medical Association a strong plea was put forward for the establishment of a register of persons qualified in electrotherapeutics; this would at least afford the public an opportunity of distinguishing between those who have been properly trained to do certain skilled work and that vague and dangerous class of individuals who set out to do similar work without such training. We understand that a move in this direction has already been made.

CONSERVATIVE TREATMENT OF APPENDICITIS IN RURAL AREAS.

"SHOULD the treatment of appendicitis in the country be surgical or medical?" This question, it will be remembered,[1] was raised by Dr. N. Nissen in the journal of the Danish Medical Association, *Ugeskrift for Laeger*, for August 23rd, 1928. His conclusion was, in brief, that in a country district, far from a hospital, it is wiser to keep the patient absolutely quiet in bed, starved, and given periodic doses of morphine, than to send him in a cold and jolting ambulance to a hospital for operation, and he added that during twenty years of practice he had treated some four-score patients on these lines without a fatality. As was to be expected, his challenge to surgery was not left unanswered, and for the rest of the year the correspondence columns of *Ugeskrift for Laeger* have borne eloquent testimony to the interest, not to say passion, which this topic is capable of arousing. One factor calculated to raise the temperature of this discussion is the interest taken in it by the general public. Denmark is a small and highly civilized country where the layman looks over the shoulder of the doctor as he writes; and, Dr. Nissen's paper being commented on freely in the lay press, the readers thereof were not slow to appreciate its import. One of the correspondents in *Ugeskrift*, an exasperated surgeon, wrote that during the last few days he had seen two patients suffering from well-defined appendicitis, and in need (so he thought) of an operation. They had both asked to be given conservative treatment according to the new system which was capable of curing appendicitis without an operation and without risk. Smiling, they had supported their requests for immunity from operation with the suggestion that a conservative treatment which was feasible in the country might conceivably be so in a town also. This question was the subject of a lively discussion in *Ugeskrift* also in 1910, and when it was debated two years ago in the Medical Society of Copenhagen one speaker, a hospital surgeon, insisted that the doctor who indulged in conservative treatment of appendicitis was guilty of malpractice to such a degree that his [illegible] should be taken from him. One of the contributors to the present discussion points out that since the question was raised in 1910 there has been a tendency to treat many more patients conservatively. But of the advantages of this treatment he is far from being convinced. While all are agreed as to the comparative

[1] *British Medical Journal*, September 22nd, 1928, p. 532.

safety of an operation *à froid*, the best means to reduce the mortality of appendicitis in the acute stage remained, in his opinion, debatable; and the aspect he wished to emphasize was the psychological one—the influence of the emotions on the peristaltic movements of the gut provoked by fear of an operation. The aid of statistics was, of course, invoked on both sides, but one correspondent argued that it must be considered impossible for general practitioners to combine in producing statistics which will be generally accepted. But is he right? Dr. Nissen's paper has already encouraged two other Danish general practitioners to commit to print the records of their cases of appendicitis treated almost entirely on conservative lines and with remarkably few fatalities. Of the statistics already available one correspondent, a surgeon, quoted those of Reedel and Sahli, showing a mortality of 10 to 13 per cent. for medical treatment. On the other hand, in Sweden, where the efforts of Lennander and Bauer in favour of immediate hospitalization and operative treatment have favoured this procedure to the almost complete exclusion of conservative treatment at home, the combined statistics of all the hospitals have shown a mortality of only 2.5 per cent. The correspondent himself, L. Kraft, had treated in Denmark during the past ten years 1,529 cases of appendicitis on surgical lines with a mortality of 4.6 per cent. (71 deaths). On the other hand, Dr. Nissen, replying to Kraft's statistical attack, carried the war into the enemy's country with the calculation that in about 20 per cent. of all operated cases the appendix proves to be perfectly healthy—an argument which would have little force were anaesthesia *plus* a laparotomy devoid of all danger. In a correspondence such as this it is interesting to note the contrast between the outlook of the country general practitioner and that of the hospital surgeon.

RESTLESSNESS IN INFANCY.

A RESTLESS baby may be suffering from indigestion or from an unfastened safety-pin, and such common causes are generally first considered. At the annual meeting of the American Medical Association last year, however, in a discussion[1] before the section on diseases of children, Dr. Hyman S. Lippman considered restlessness in a much more scientific manner. Restlessness is one of the symptoms of the hypertonic baby who is "hyperactive, fussy, and restless, cries most of the time, vomits considerably, and has frequent loose stools." The cause of this hypertonicity is not known, but it appears that modern views favour either "congenital imbalance of the autonomic nervous system" or some unsettling factor in the post-natal environment, such as feeding or the emotional attitudes of the parents. Lippman has studied a group of 63 infants with an average age of 7 weeks. In this group the gain in weight was less than in a control group of normal children; vomiting and diarrhoea were frequent, and restlessness and crying occurred in 82 per cent. during the day and in 51 per cent. during the night. Holding to the essential nervous origin of these cases, he used atropine almost entirely as his therapeutic agent. The infants were observed, with a few exceptions, for one to two weeks before treatment with atropine was instituted. During this preliminary period various other measures were tried, including change of diet, complementary feedings, temporary removal from the breast, holding the infant over the shoulder to relieve air-swallowing, and keeping the infant in a quiet, darkened room away from visitors. Fifty-nine of the experimental group were then given atropine, beginning with half-drop doses of a 1 in 1,000 solution of atropine sulphate ten minutes before feeding. All precautions were taken to ensure the potency of the drug, and in 44 of the infants definite improvement was noted. In 24 of these the response was so prompt and the relief of symptoms so complete that Dr. Lippman is convinced that the drug acted as a specific. In 9 cases it was decided to check the value of the medication by omitting the drug, and in 7 of these the original symptoms returned, while in the remaining 2 the atropine appeared to have effected a cure. The length of time that the atropine must be used varies for each infant. Five infants were relieved within two or three days, but in most instances it was necessary to give the drug for a week at least, and if no relief had been obtained the dosage was increased. Eleven of the 63 infants failed to show any improvement with the use of atropine, and in these it was believed that other factors were present, of which the most important was air-swallowing due to restlessness while at the breast. Lippman points out that restlessness in infancy often leads to emotional difficulties in the older child, and he stresses the importance of the correct balance of the autonomic nervous system from the earliest days of life. His views command respect, but it also seems important, when concentrating on vagus nerve endings, not to forget the uncomfortable napkin or tight binder.

[1] *Journ. Amer. Med. Assoc.*, December 15th, 1928, p. 1848.

PAIN.

THE symptom of pain, which in clinical medicine and surgery is so important an aid in making a diagnosis, is peculiar in that it cannot be directly observed or measured. No norm exists whereby the pain of one patient may be compared in kind or in severity with that of another; even the existence of pain, except when it is unhappily the datum of one's own consciousness, must be inferred from the presence of concomitant phenomena, which themselves, however, are not pain. Most people know what toothache is like, but who can tell whether his own particular toothache is more or less severe than that of another? It may be argued that the reaction to pain is a trustworthy index of its quality or of its intensity, but one may well question whether the person who makes the greatest fuss is necessarily suffering the most. It used to be said that before the days of surgical anaesthesia in a certain hospital which ministered to people of various races, it was the labouring Irishman and the Jew who made the most noise on the operating table. Neither race was supposed to lack endurance, but it was held that the Hebrew cried out through fear that if he failed to attract full attention he might miss some of the benefits of hospital care; while the Irishman called loudly upon God and the saints, and wept and groaned, because he was an emotional being to whose nature the repression of feeling, whether pleasant or painful, was foreign. Neither was a coward, but the one had learnt the bitter lessons of persecution, and the other lacked adequate psychological inhibitions. Consideration of the moral significance or value of pain—a subject on which a member of our profession, James Hinton, wrote a memorable work, *The Mystery of Pain*—belongs to the domain of metaphysics and theology, but we who are devoted to natural philosophy may well be concerned with pain in its physiological and pathological aspects. It seems obvious that the pain following a breach of continuity or injury to the cutaneous outpost of the body is one of the expedients of a highly evolved protective mechanism. When the epidermis is penetrated and the true skin outraged the cutaneous terminations of protopathic nerves flash out the message of danger, and the consequent reflex muscular action results in the withdrawal and protection of the part from further injury. Here the biological value of painful stimuli to the organism is obvious, but only too often pain, even excruciating and persistent pain, appears to subserve no such protective function. Interesting in this connexion is the pain from

the exposed pulp of a carious tooth. What useful purpose does it serve? It may, and does, stimulate the sufferer to seek the dentist's help, but this expedient was probably not available to Neanderthal man, and was certainly not to the orang-outang. Yet both these creatures suffered from dental caries. Again, what use is a pain in the shoulder-blade to a man with a disordered liver? How does the agony of biliary colic help the sufferer to overcome the obstruction in his gall-duct? How, indeed, was prehistoric man helped by referred pains to obtain relief from the various morbid states associated with them? The teleologist might perhaps argue that the association of pain in a given skin area with disease of a viscus having the same segmental nerve supply is a protective provision, designed to enable the surgeon to arrive at a correct diagnosis. But of what use were such pains in the days before Head demonstrated the connexion between them and disease in deeper organs?

VARIATIONS IN WORK DONE UNDER TUBERCULOSIS SCHEMES.

THE circulation by the Ministry of Health of an analysis (Memo. 131 A/T.) of the work done in 1927 under tuberculosis schemes in England should be of considerable value to local authorities, providing them with standards which will enable them and their officers to estimate the efficiency and economy of the services they provide. It is perhaps unfortunate that the document presents a somewhat forbidding aspect to those who dislike figures, consisting mainly, as it does, of tabular information relating to about 160 local authorities with details, grouped under no fewer than forty-two headings. Before this serried mass of figures many will no doubt quail, but it is to be hoped that at least those directly associated with the administration of tuberculosis schemes will scrutinize the figures relating to their own areas and compare them with others. The value of such compilations is that they furnish opportunities for self-criticism, and enable those engaged in tuberculosis work in one area to form a clear idea of what is being done elsewhere. It is impossible to offer a summary of the matter contained in the memorandum, but a few examples will serve to indicate the nature of the questions it raises. In connexion with dispensary work the table shows that the number of contacts examined by the tuberculosis officer per 100 deaths from tuberculosis was in one county 585 and in another only 23, while for all county councils (excluding London) and joint committees the figure was 104, and for England as a whole 116. Clearly such a wide divergence from the mean as is given by the county figures calls for some explanation; there are evidently very considerable differences in the extent of the service provided. It is possible that both schemes err—one in carrying the practice beyond what is necessary, and therefore being over-costly, and the other in failing to develop an important feature of the work. Possibly, also, differences in local conditions may provide a complete explanation, but on the facts given this does not appear likely. To quote a further example, the number of cases on the dispensary registers per 100 cases on the notification registers at the end of 1927 was 58 for all England; for particular areas the figures range from 15 in a metropolitan borough to 98 in a North of England county borough. These figures show the proportion of the total tuberculous population in each area which was dealt with under the tuberculosis scheme, and here again the differences between one district and another are impressive. Even wider differences are shown in the figures given as an index to the extent of co-ordination in the work of tuberculosis officers and insurance practitioners in the domiciliary treatment of insured persons suffering from tuberculosis. The number of reports received on Form G.P. 36 per 100 patients on domiciliary treatment varied from 0 to 586. In connexion with institutional treatment particulars are given of the number of patients treated (excluding observation cases) per 100 tuberculosis deaths; for all county councils (excluding London) and joint committees the figure is 106, for all county borough councils (except those included in joint committees) it is 157, for London it is 114, and for all England 119. In two areas the proportion is as low as 40, and in one it is as high as 557. It is not suggested that the figures given, or those from which they have been selected, in themselves afford ground for condemning certain local authorities as backward or extravagant, or for praising others as progressive and efficient. The surprising differences in the figures do, however, show conclusively that the development of tuberculosis schemes has been very uneven, and the extent of the variations in the work done makes it equally obvious that in many areas the service is far from complete.

LEPROSY IN MEXICO.

THE Public Health Department of the Republic of Mexico has recently issued a report[1] containing the results of the first census of leprosy to be taken in that country, edited by Dr. Jesús González Urueña, a well-known dermatologist. The statistics are based on the replies received to questionaries sent out to all the medical practitioners throughout Mexico, as well as to the governor of each State. The points on which information was desired were the number of cases in the various States, the character of the disease, and the age, sex, birthplace, present habitation, environment, and civil state of the patients. The results of the inquiry in each of the States are given according to their alphabetical order. It is admitted that the statistics are by no means so complete as they would have been in a more civilized country, partly because out of the 2,756 doctors circularized only 1,406 sent any replies, and partly because some districts were entirely without doctors. The total number of lepers returned amounted to 1,450, or one for every 4,797 inhabitants, a figure probably not reached by any European nation, excepting Norway, with an incidence of one leper for every 4,266 inhabitants, and in America only exceeded by Colombia, Dutch Guiana, and Brazil. The largest number of cases were returned from the State of Jalisco, which contained 202, while Tlaxcala, the smallest of all the States, was the only one entirely free from the disease. In Mexico, as in other countries, leprosy shows a ubiquitous distribution. It is found not only in tropical climates, such as that of Yucatan, but also in temperate and cold zones, such as the Federal District and the States of Guanajuato, Jalisco, Michoacan, and Coahuila. In conclusion, we may add, for the benefit of those not familiar with Spanish, that Dr. Urueña's report contains a coloured map showing the distribution of cases throughout the country.

DANGERS OF COD-LIVER OIL.

THE knowledge widely disseminated among the public of scientific work on nutritional disorders has led to much administration of cod-liver oil without the agency or control of the doctor. Many parents believe that the larger the dose and the longer it is continued the better for the child. The work of Agduhr on the toxic changes produced in experimental animals with doses of cod-liver oil per kilogram of body weight corresponding to or even less than those not infrequently employed for children has already been mentioned in these columns.[2] Following upon this work Dr. N. Malmberg has recently published[3]

[1] *Primer Censo de la Lepra.* Mexico: Departamento de Salubridad Publica. 1927. (Pp. 565.)

[2] *British Medical Journal*, 1928, i. 639.

[3] *Acta Pediatrica*, viii, Fasc. 3, December 22nd, 1928, p. 364.

his findings in two cases of young infants dying after cod-liver oil medication. One of these was a premature baby who from the time of birth until death at the age of 4 months was in a hospital, where the diet and general care were under constant supervision. A weakly child at first, it appeared to thrive for a time, and then died without any obvious or acute symptoms except generalized oedema and debility during the last three weeks of life. It received half a teaspoonful of cod-liver oil twice daily until the age of 6 weeks, and then a teaspoonful twice daily until death. Histological examination of the heart showed atrophy and different forms of degeneration, even to the point of necrosis of the muscular cells. The changes agreed in a striking manner with those experimentally produced in animals by Agduhr, and to check the results Malmberg examined the cardiac muscle of other premature children without finding any such changes. In a second case, also a premature baby, the presence of a spina bifida with paralysis in the lower limbs and incontinence of urine made the outlook hopeless from the start, so cod-liver oil was given in large doses until the death of the child on the sixteenth day of life from urinary tract infection. Histological examination of the heart showed simple atrophy of the muscle cells with areas of sarcolysis and vacuolar degeneration. In both cases it is possible that terminal infection might have been responsible for the striking changes in the heart muscle, but such marked atrophy and even secondary replacement of connective tissue as was present appear to rule out any terminal change of short duration. The prematurity of both infants is also a matter of comment, for Agduhr showed that animals varied greatly in their susceptibility, and it is possible that there may be an intolerance of cod-liver oil in some infants. It is admittedly a difficult matter to determine with any degree of accuracy the minimum dosage of cod-liver oil necessary to prevent rickets in different children, and it is, moreover, uncertain whether the vitamin or something else in the oil is responsible for the pathological changes. Is it possible, for example, that contributing to the toxic symptoms was a ketosis produced by excessive fat feeding, and that similar results might have been obtained by feeding with fats other than cod-liver oil? Dr. A. A. Osman, in a paper on debility in children, published in our present issue (p. 150), suggests that many cases of so-called debility in children are due to ketosis, and curable by adding to the diet adequate quantities of glucose. It would seem to follow that treatment of such cases with cod-liver oil, by tending to increase the ketosis, might exacerbate rather than relieve the existing symptoms. Agduhr suggested from his work that even purified antirachitic extracts of cod-liver oil were not without danger; but the interpretation of his results must remain in doubt until control experiments have been carried out with each of the constituents of cod-liver oil separately. At present, however, the lesson of his experimental findings and the pathological findings in infants reported by Malmberg is that cod-liver oil is a potent substance for good or evil, and that its use as a medicament needs careful supervision.

FERNAND WIDAL.

PROFESSOR FERNAND WIDAL of Paris, whose death was announced in our last issue, was born at Dellys in Algeria on March 9th, 1862, the son of a medical inspector of the French army and director of the health service of the 19th Army Corps. He was educated in Paris, where he gained the gold medal in the examination for the *internat*, and later was awarded the Osiris prize conjointly with the late Professor Chantemesse. He was first appointed professor of pathology, and subsequently, on the death of Professor Dieulafoy in 1911, professor of clinical medicine in the Paris faculty. His discovery of bacterial agglutination and its application to the diagnosis of typhoid fever was published in 1896, and his work on the treatment of Bright's disease in 1906. Since the war he had paid special attention to the study of functional tests of the liver and of asthma, anaphylaxis, and kindred subjects. He was author of articles on infectious diseases in the *Traité de Médecine* of Bouchard and Brissaud (1899), and was co-editor, with Professors G. H. Roger and P. J. Teissier, of a *Nouveau Traité de Médecine*, of which twenty-two volumes have appeared, and to which he contributed, in collaboration with other writers, the articles on typhoid and paratyphoid fevers, affections of the kidneys, and haemoglobinuria. Professor Widal was elected a member of the Académie de Médecine in 1906, and of the Académie des Sciences in 1919, honorary Fellow of the Royal Society of Medicine in 1921, and foreign member of the Royal Swedish Academy of Medicine in 1922.

THE Metropolitan Counties Branch of the British Medical Association has arranged a meeting, to be held at the British Medical Association House, Tavistock Square, W.C.1, on Friday, February 15th, to which all fourth and fifth year medical students and recently qualified medical practitioners are invited. Tea and coffee will be served at 5 p.m., and at 5.30 Dr. Ronald Cove-Smith will give an address entitled "Some gaps in the medical curriculum and how we can fill them."

THE KING'S ILLNESS.

IF last week we could write with some optimism of His Majesty's progress, optimism is still more justified now. It is true that in the intervening days there has been no dramatic change in the general condition; rapid improvement was not anticipated, and its absence in no way alters our view that at last a more favourable prognosis may be made. Since December 28th the outstanding fact is that there has not been even a hint of a setback, while every now and then His Majesty's medical advisers have felt themselves justified in recording some slight, though definite, change for the better. When we look back to the period when almost every authoritative medical statement enjoined an anxiety that was only too justified by the critical nature of the illness and the state of the patient, when for days at a time hope was difficult to sustain, we can contemplate the present with deep-felt thankfulness.

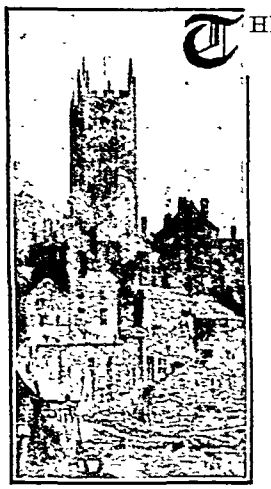
We have said that there has been no dramatic improvement in the general condition; but this is true only if one measures the day-to-day increments of improvement. Who, knowing the nature of His Majesty's illness, and aware of the usual prognosis in a general streptococcal infection complicated by broncho-pneumonia and empyema, could have ventured to predict at the onset that in eight or nine weeks the patient would be fit to be moved to the sea coast? One has but to compare the bulletin of to-day with those of a few weeks ago to realize how striking the improvement has been. Only the combination of a sound constitution, the will to live, and perfectly co-ordinated medical care could have achieved this. All danger of setback is not yet over, but we dare to hope that at last the tide has turned definitely in His Majesty's favour, and that the latest measures adopted in his treatment will bring the stage of convalescence appreciably nearer

NINETY-SEVENTH ANNUAL MEETING

of the

British Medical Association,

MANCHESTER, 1929.



THE COLLEGIATE CHURCH, MANCHESTER.

THE ninety-seventh Annual Meeting of the British Medical Association will be held in Manchester next summer under the presidency of Mr. Arthur H. Burgess, F.R.C.S., Professor of Clinical Surgery in the University of Manchester, who will deliver his address to the Association on the evening of Tuesday, July 23rd. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days, the morning sessions being given up to discussions and the reading of papers, and the afternoons to demonstrations. The Annual Representative Meeting, for the transaction of medico-political business, will begin on the previous Friday, July 19th, at 9.30 a.m. The preliminary arrangements for the work of the nineteen Scientific Sections have been made by a special committee, consisting partly of Manchester representatives and partly of members appointed by the Council of the Association. The names of the officers of Sections were given in the *Supplement* of January 12th, and further details of the arrangements for the Annual Meeting will appear in later issues. During the week, and in particular on the last day of the meeting (Saturday, July 27th), there will be excursions to places of interest in the North-West of England. The British Medical Association has met four times at Manchester—in 1836, in 1854, in 1877, and again in 1902. We publish below the second of a series of descriptive and historical notes on Manchester and neighbourhood written for the occasion. The first article appeared on December 1st (p. 1003).

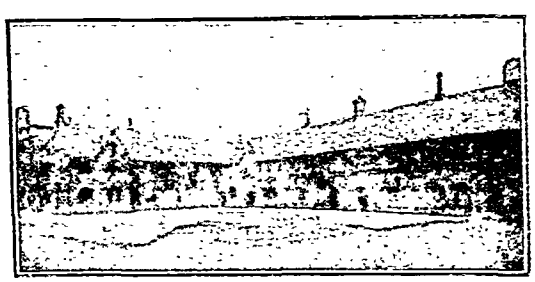
HISTORY OF MANCHESTER.

BY

E. M. BROCKBANK, M.D., F.R.C.P.

MANCHESTER owes its prominence in the industrial world to its position on the slopes of the Pennine Hills as they run towards the western coast and the Atlantic Ocean. Its original situation was at the junction of two rivers, the larger being the Irwell, into which ran the smaller Irk, now entirely hidden by extensive culverting. Both streams arise in the high lands and drain an area of what was once an extensive tract of bog, forest, and waste lands.

There is a high outcrop of red sandstone rock in the angle of the confluence of Irk and Irwell, and it was at this spot that the original settlement was formed, the manor house of Manchester was built, and from which the town subsequently developed. The river angle was further protected by an artificial ditch, traces of which still remain in basements of the buildings over its site. The Manchester Cathedral and the Chetham Hospital and the Grammar School have occupied the angle of the river junction since their foundation. The site was of great importance because of its water supply and because it commanded the agricultural land and roads of the foothills which intervened between the Pennines and the very extensive boggy lands south-west of the town, which constituted what are known as Carrington and Chat Mosses, referred to in Harrison Ainsworth's novel *Guy Fawkes*, which has some of its action in this district, and over which George Stephenson had such difficulty in making a track to bear the Manchester and Liverpool Railway.



CHETHAM'S HOSPITAL AND LIBRARY.

Such a position as that called by them "Mancunium" attracted the Romans because of its defensibility and because it commanded important roads. It was on their direct line of march between their headquarters at Deva (Chester) and Eboracum (York); from it a road ran to Coccium (Wigan), which was on the main Roman north road, just as it is now on the main L.M.S. railway line to Scotland; and another road to Bremetennacum (Ribchester), an important Roman centre in North Lancashire, on the high road from Mancunium to Lugdu-vallum (Carlisle). The Roman camp was, however, a mile lower down stream, at the junction of Medlock and Irwell, a district called Alport, again a position well elevated above the rivers. The only trace of the camp now remaining is a small part of a wall, which is protected by the city from further injury. The site of the camp is still known as Castlefield.

The earliest mention of the town in reputable history occurs in the *Anglo-Saxon Chronicle*, 923. When Edward the Elder was reconquering Mercia from the Danes he sent a detachment of troops to Mameceaster to repair and man it. The rock site in the junction of Irk and Irwell was also a desirable place because the Irwell was there fordable by the Sal ford. The expulsion of the Danes forms the subject of one of the Ford Madox Brown panels in the Town Hall, which illustrates some incidents in our history.

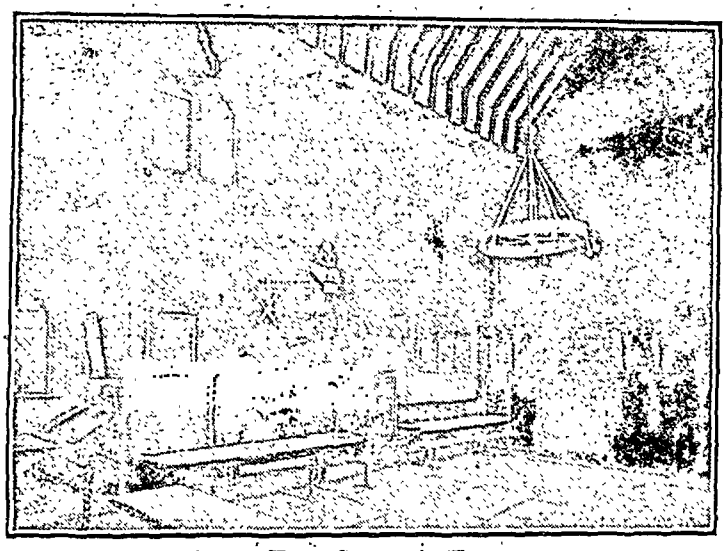
Mameceaster and Salford are referred to briefly in Domesday Book: "King Edward held Salford. There are

three hides and twelve carucates of waste land. There is a forest three leagues long and the same broad. There are many hays [enclosures] and an aerie of hawks there." "The Church of St. Mary and the Church of St. Michael hold in Mamecestre one ploughland free from all burdens save Danegeld." The Church of St. Mary, the earliest church in the neighbourhood, was a wooden building occupying the site of the present Cathedral. St. Michael's Church is at Ashton-under-Lyne, which was then in the parish of Manchester.

A century or two later Manchester is recorded as having aeries of hawks and eagles and a heronry in the woods in the Roman camp district, where, alas! nowadays we can only show rookeries, and treeless ones.

In the days of Edward the Confessor, before Domesday Book time, Manchester formed part of what was then the royal manor of Salford, which was the centre of a great hundred of Salford, 350 miles square, afterwards often called Salfordshire, which composed the whole of the basin of the Irwell and its tributaries. Salford County Court circuit still includes Radcliffe, Bury, Rochdale, Oldham, and Bolton in its jurisdiction. This hundred and other extensive lands between the Mersey and the Ribble were granted as royal demesne to Roger the Poitevin by William the Conqueror.

The township of Salford, though on the right bank of the Irwell, lay in the ecclesiastical parish of Manchester, and before the Crown grant to Roger the Poitevin the King's manor house at Salford had been the civil centre of the district which had St. Mary's Church on the left bank of the river for its ecclesiastical centre. It was in the eleventh century that the town charter was received (and not in the fourteenth century, as my former sketch of the relations of the two towns suggested), and during Roger's tenure that the great part of the parish on left bank of the river, with the exception of Broughton, was cut off from Salford demesne and given as a manor to an under-tenant in return for military service. Roger retained Salford in demesne, and it has since been held by the Sovereign as part of the Duchy of Lancaster. The reigning Sovereign is therefore lord or lady of the manor of Salford, and the Crown is thus toasted in Salford by royal permission. Professor Tait, from whose most interesting work on mediaeval Manchester much of my history is taken (as shamelessly as Homer is said by a soldier critic to have obtained what he thought he might require), says: "Thus a stroke of a Norman baron's pen divorced Manchester and Salford in all but their devotions, and what he sundered no one has been able to bring together again."



DINING HALL, CHETHAM'S HOSPITAL.

Manchester thus became a barony, and the first baron about whom anything definite is known was Albert Grellet, or Gresley, said to be a favourite of Roger the Poitevin. The manor house, as before mentioned, was built on the safe angle of Irk and Irwell junction. Grellet's name appears in Domesday Book as Albertus Greslet. The name Greslet was probably an instance of Norman love for giving distinctive names from some personal appearance, or behaviour, complimentary or otherwise, many of which, as Professor Tait tells us, are to be found in Domesday Book. Some of these were retained as surnames; for instance, "The Fair" became Blount or Blunt, and amongst the Earls of Cheshire, Hugh Lupus (the Wolf) and Randle Gernons (Mustachios). In humbler circles such names as William (not George), who cannot tell a lie (spernens mendacium), appear. Greslet had probably such an origin, and may have meant spotted or pock-marked, or slim of figure.

The Grelleys were absentee landlords, living on their Lincolnshire estate, and the great-grandson of the first Robert married a niece of William Longchamp, Richard I's Chancellor, and Regent during the King's absence. He joined the barons in extorting the Magna Charta from King John, and suffered forfeiture in consequence. However, there was a certain amount of balancing of accounts later, because it was in the Abbey at Swineshead, on the Lincolnshire estates of the Grelleys, that John had his surfeit of peaches and beer which caused his death.

The last of the Grelleys gave a town charter to Manchester in 1301, with power, amongst other things, to elect a burgess to the honourable position as head of the community; it was merely a confirmation of existing privileges. The town adopted the crest of the Grelleys on its armorial bearings. Salford had previously received its charter in 1231. The Grelley line died out in 1311, and the manor rights passed into the possession of relations and others until they were sold in 1596 for £3,500 to Sir Nicholas Mosley, a Manchester man, but a merchant and thrice Lord Mayor of London. The manor rights remained with the Mosleys until 1845, when they were purchased by the Corporation of Manchester for £200,000. Our Mosley Street is a reminder of these lords of the manor.

Thomas de la Warre, who married Joan Grelley and owned the manor, was rector of Manchester. He was much concerned with the inadequacy of the clerical staff in the huge parish covering 350 square miles, so, in 1421, he obtained royal licence to substitute a college of a warden and eight clerical fellows for the rector, and the church became collegiate. The clergy lived for a century on the site of the old Barons Hall, in the building which was subsequently purchased in 1654 by the will of Humphrey Chetham, a Manchester cotton merchant. Chetham then endowed the old hall to become the first public free library in England and as a hospital for the maintenance and education of forty poor boys, a purpose which it still nobly fills in its almost unchanged, mediaeval form. The boys, now numbering one hundred, are still to be seen in their original blue coat costumes.

Another foundation for education in the Irwell-Irk angle adjoining the Chetham Hospital was the Manchester Grammar School. Founded in 1515 by Hugh Oldham, a Manchester man, then Bishop of Exeter, it is one of the oldest public schools in England. Oldham was a close friend of Bishop Foxe of Winchester, and helped him to found Corpus Christi College, Oxford, and provided most of the money for it. He endowed the school as a feeder for the college, and also provided help for boys going from the school to any college at Oxford or Cambridge. Corpus Christi College still has a representative on the board of governors of the school.

After receiving its charter the town led its mediaeval life much as other English towns, with certain crafts of milling, fulling, spinning, weaving, and dyeing. Agriculture was, however, the chief occupation for some centuries until the persecution of the Spaniards in the Netherlands and of the Catholics in France drove many Protestant craftsmen to England. Some settled in Manchester and neighbourhood because of its water resources, and this incident also forms the subject of one of the frescoes in the Town Hall. In this way, amongst other trades, the spinning, weaving, and dyeing of wool and flax which was carried on in the town received a great stimulus. Leyland, visiting the neighbourhood in 1536, describes Manchester as "the fairest, best builded, quickkest and most populat towne of all Lancastreshire"; and Defoe, two centuries later,

in his tour through Great Britain (1724–26) visited Manchester and described it as "one of the greatest if not really the greatest mere village in England." The population then was below the 22,000 of 1770.

COTTON.

It was during the sixteenth century that "Manchester cottons" became known as a desirable article of trade. They were known under this description in Rouen in 1553. They were also known as fustians, a name derived from the Fustat quarter of Cairo, where similar goods were woven. Manchester cottons were at first only made of wool, linen, and some silk, but about 1600 a new material was introduced into the town, according to a petition of London merchants—"a kind of bombast or down being a fruit of the earth growing upon little shrubs or bushes brought into this country from Smyrna, Cyprus, Acra, and Sydon, but commonly called cotton wool."

Cotton is the Anglicized form of "kutun," which was the Arabic word for the new material. Each cotton fibre is the outgrowth of a single cell of the outer coat of the seed of the cotton plant, and important features about it are that it is a thin-walled, somewhat elastic tube sealed at both ends with a natural twist on its own axis and with varying diameter. These natural characteristics make cotton the easiest of all materials to twist into a thread, and consequently so cheap for cloth making that it is said that nine-tenths of the clothing of the world is made from it.

Cotton must have been spun in hot Eastern countries where the plant grew since artificial clothing became necessary. It was always done by hand, twisting the fibres with the fingers into a single thread, which was wound on a spindle or a wheel. This primitive process of cotton spinning continued wherever cotton was used, and only one thread, or at the most two threads, could be spun at a time until the middle of the eighteenth century, when the genius of a few Birmingham and Lancashire men revolutionized the whole industry of spinning and weaving cotton, and led to the production of machines on which 1,200 spindles, instead of one or two, can be rotated at then unthought-of speeds.

CHETHAM'S HOSPITAL: ENTRANCE TO CLOISTER COURT.

The impetus to these inventions came in 1733 from John Kay's flying-shuttle, which enabled the weaver to work much quicker and to weave wider cloths. Before Kay's invention, which was a very simple one, the weaver had to lend over his cloth and throw the shuttle by right and left hand alternately from each side through the loom. Kay put a "stick" into the weaver's hand, from the free end of which cords went to both sides of the loom, where they were attached to a metal weight which could be jerked forcibly by movement of the stick and cord against the shuttle, and so knock it through the loom to the other side, when an opposite movement of the stick sent it back through the loom. The principle is still in widespread use in the mechanical loom of to-day.

At that early period of the introduction of machinery every contrivance that increased production was looked upon by the workpeople as certain to deprive them of their means of existence: consequently they endeavoured to wreck all such new inventions. This wrecking was a frequent theme of Victorian novelists, as witness *Shirley* and *John Halifax, Gentleman*, to mention but two instances. A mob succeeded in wrecking the flying-shuttle, but only for the time being, for, like many inventions which decreased the cost of production, it increased the demands for a cheap material, and was therefore a means of additional employment.

Before Kay's time all the cotton was spun by hand, and there was no real increased demand for the new shuttle until twenty-five years after its invention, during which time mechanical spinning and weaving revolutionized the cotton industry. Although East Lancashire and West Cheshire are now the centres of the mechanical cotton-spinning industry, and most of the present-day machinery was invented or perfected there, the first useful steps towards substituting machines and artificial power for the human finger and muscles were taken at Birmingham. There Lewis Paul, in 1738, patented a machine in which successive pairs of rollers moving at different speeds attenuated a thick rope or roving of cotton fibres, which was prepared by hand, into a finer thread or yarn. He also patented (1748) a most important combing machine to prepare this preliminary roving. With these machines Paul started mills in London and in Birmingham, and, although the inventions were said not to be of much practical use, he made £20,000 out of them. Real progress in mechanical spinning was first achieved by three Lancashire men — James Hargreaves of Blackburn, who patented in 1767 the first commercially successful machine, called the "jenny," which could spin many threads at a time when driven by hand power; Richard Arkwright, born in Preston, but working in Bolton (1769), who improved Paul's roller drawing and combing machines to make them of real value, and applied first horse, then water, power to them; and lastly, Samuel Crompton of Bolton, who combined in one machine, called a mule, the essential features of Hargreaves's jenny and Arkwright's roller drawing machines. On one of these wonderful machines can now be spun on 1,200 spindles (not one only as aforetime) thread so fine that more than 150 miles of it may weigh only one pound.

With these machines so much cotton thread was produced that the looms worked by hand labour could not use it, even when the fly shuttle was adopted by weavers. The difficulty became known to Dr. Cartwright, a Leicestershire clergyman, who came to the rescue with the invention of a power loom, driven at first by a bull, and later, as he improved it, by water and steam (1790). The loom could then do with all the yarn produced in the mills, and the prosperity of operatives and owners and of Lancashire began.

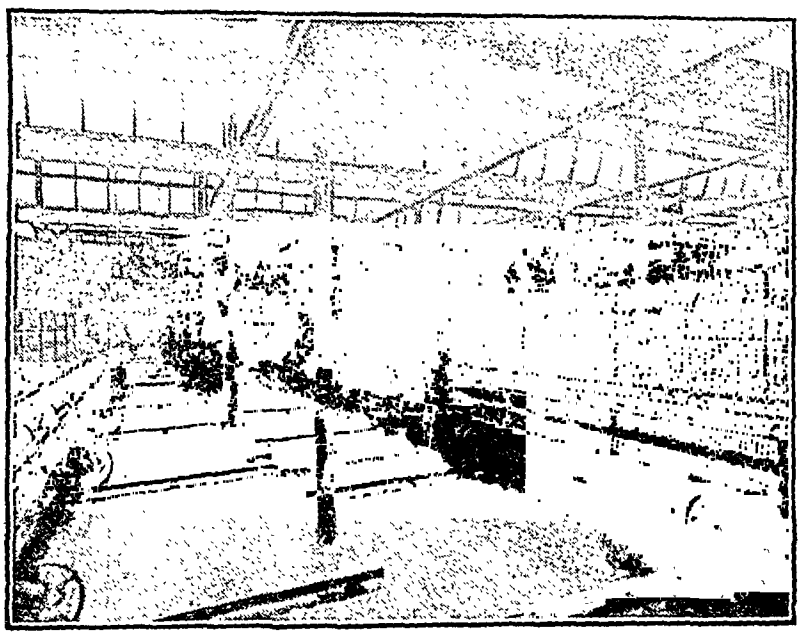
Spinning and weaving machines at first were worked by hand power, adult and child, in the people's homes; later they were driven by water power in mills set on the banks of streams, and so began the great mill industries of Lancashire valleys. Finally, in 1789, steam was used for power in cotton mills for the first time in Manchester. Such was the impetus given to the cotton industry by these inventions that the human labour for the mills of the district was soon exhausted, and it had to be imported from other parts, often from the workhouses of London and other large towns. The population of Manchester, in consequence of the increase in the cotton industry, grew from 22,000 in 1773 to 45,000 in 1788 and 70,000 in 1800, and sad indeed were the conditions of life among the working classes and the abuses of child labour by parents

and manufacturers. The hours of child labour in mills which ran night and day were unrestricted by law, and there was no supervision of the mills by factory inspectors.

PUBLIC HEALTH.

The result was, naturally, serious ill health in the cotton operatives, and such outbreaks of typhus fever occurred that the leading citizens became alarmed, and with the support of some of the medical men of the town, especially Dr. Thomas Percival and Dr. John Ferriar, formed a committee of public safety, or board of health, in 1796, the first of such committees to be formed in England.

Among the good employers who thought of the welfare of their workers, especially of the children, were the Grants, the prototypes of the Cheeryble Brothers of *Nicholas Nickleby*. Public action led also to factory legislation, and it is interesting, if sad, to read some of the evidence—venal, one would almost say suborned, on their own acknowledgement—given by medical men on the hours of labour of children. Let me get the worst over at once. One, a Manchester doctor giving evidence for the masters before a committee of the House of Lords, said he could not give any number of hours below twenty-four which might be above or below the line of which a child (of 6 or 9 years of age) could work without suffering. A surgeon and apothecary of Bingley in Yorkshire did not think that a little recreation or amusement during the day was contributory to the health of young persons. Fortunately, others thought that the hours of working of a person under 16, exclusive of the time allowed for meals, ought not to exceed *nine* hours in winter and *ten* in summer; and it was a question whether, with impunity, the strength of adults was capable of much longer exertion than this.



MACHINERY IN A MODERN COTTON MILL.

As I said in the opening line of this account of the development of Manchester, its geographical situation has had much to do with its commercial success and in making it the leading town in the cotton trade of the world. The district known as East Lancashire and West Cheshire, lying between the hilly background of the country and the western ocean, has a temperate, equable, and moist climate, one which is ideal for cotton spinning and weaving, and especially for producing the finest cotton products, for which Manchester is celebrated and unrivalled in any part of the world. The annual rainfall is only 36 inches, but Manchester has the reputation of being a wet place, especially among our gentlemen friends of Liverpool—Manchester men, Oldham lads, fellows from Rochdale, and Liverpool gentlemen, as the local saying is. As president of the Manchester Medical Society I attended the annual dinner of the Liverpool Medical Society, and exchanged a few stories with a legal guest. With magnetic guile he drew me on to talk of weather, and I said our rainfall was not so bad as Liverpool's. On replying for the guests he opened in courteous terms about his neighbour from Manchester who had told him some wonderful stories which he did not care to repeat, but amongst other things "he actually asked me to believe that Liverpool is a rainier town than Manchester." It was the speech of the evening. In addition to the plentiful supply of water, Manchester is in the middle of a rich coal-bearing district, which made steam power cheap, and it was close to a maritime outlet on the Mersey. Dr. W. F. Dearden has shown in his Milroy Lectures on the Health Hazards of the Cotton Industry how even the slight differences in the atmospheric content of water which occur in the large cotton manufacturing towns affect the fineness of the article which is manufactured in them.

The poor conditions of life of all the labouring classes in the eighteenth century were greatly improved in time by the development of the cotton industry. Much more money, small in total indeed though it was, reached a home by the earnings of those members of the family who worked in a spinning mill and those who were at home, and there was, consequently, more money to be spent on necessaries of life—food and clothing, boots, etc. Trade generally, therefore, was improved. Between 1760 and the Reform Bill (1832) the output of cotton manufactures increased one hundredfold, and in 1806 it was said to supply one-third of the total of British exports. The cotton trade, directly and indirectly, played a very great part in meeting the heavy National Debt incurred after the Napoleonic wars. It is said that Arkwright offered to finance the Government in the wars with France if they would continue his patent rights for a number of years.

The opening of the Duke of Bridgewater's canal, which brought coal from his pits at Worsley to Manchester at cheap rates, was a great help to steam power, and when the canal was extended to Liverpool, in 1772, this cheapened cotton at a time of great need for it. A further event of great importance to the cotton trade was the opening of George Stephenson's railway between Manchester and Liverpool in 1830. This was a great national event, with the Duke of Wellington present; it was marred by an accident which proved fatal to Mr. William Huskisson, one of the promoters of the railway and a member of Parliament for Liverpool. There is a marble tablet to his memory and the incident on the railway by Parkside, which he who travels may see. The original terminus of the railway is still in use in Liverpool Road, Manchester, where it forms part of the railway's goods department.

IMPORTANCE OF THE COTTON INDUSTRY.

Manchester is the centre of the cotton industry of the kingdom. Included in the industry now is the new material called artificial silk, which is having a very great influence on the trade when mixed with cotton in manufactured materials.

It is estimated that no fewer than 10,000,000 of the population of Great Britain are directly and indirectly dependent on the cotton trade for their daily bread, so great are the ramifications of the trade, the interdependence of one industry upon another, and the "wheels within wheels" of commerce. The cotton trade depends almost entirely on the export trade, and cotton goods comprise nearly one-third of all our exports of manufactured goods. The value to our home trade in cotton goods is estimated at only about one-fifth of the whole cotton trade. In 1927 more than 4,000,000,000 square yards of woven cotton goods, valued at £110,000,000, and over 200,000,000 lb. of cotton yarn, valued at nearly £23,594,000, were exported.

The profits from the cotton industry do not end with those received from the actual selling price of the finished material, yarn or cloth. There is, in addition, the cost of insurance, financing, freight, and merchants' commission and profits, almost all of which are a profit earned by this

country, and over £500,000,000 capital is engaged in, or directly dependent on, the trade. If the cotton trade ceased to exist to-morrow Great Britain would become a third-rate power, from a commercial point of view, and probably at least one-fourth of the population would have to emigrate, as it would no longer be possible for them to earn a living in this country. There is no other manufacturing export industry, either in this country or in any other part of the world, which can be compared with the cotton trade; and it enables Great Britain to pay for a large portion of the meat and grain and commodities which she has to purchase from other countries.

After the cotton industry in importance come the engineering, chemical, and rubber industries of the town and neighbourhood. A great factor in the development of the business of the town has been the influence of the Ship Canal, by means of which 15,000-ton ocean-going steamers can get into the heart of the city and bring the raw materials, food, and other goods which pay for the cost of manufactured articles sent abroad, and of the insurance, freight, and financing of the trade. Six and a half million tons of goods are brought to, or carried away from, Manchester and Salford in a year now by the Canal. Direct sailings are made from the docks to and from the chief ports "in all the seas of all the world."

Manchester has contributed to the enrichment of the country in other ways than those of commerce; but that is another story which awaits its telling.

Scotland.

Future of Hospital Services in Scotland.

A MEETING of the Voluntary Hospitals Liaison Committee was held on January 16th, on the invitation of the Department of Health for Scotland, in the offices of the department at Edinburgh to consider the bearing of the Local Government (Scotland) Bill on the future of the hospital services, particularly those of the voluntary hospitals. Dr. Walter Elliot, Parliamentary Under Secretary of State for Scotland, and officials of the department, were present. The meeting reviewed various suggestions for a clause designed to remove the Poor Law stigma from treatment in the hospitals which are at present under Poor Law administration; it was unanimously agreed that this was desirable, and that public bodies should be given power to provide hospital treatment apart from the Poor Law. It was considered essential, however, that adequate safeguards should be made to protect the voluntary system, and the attention of the meeting was mainly directed to finding a form of words which, embodied in the bill, would achieve this purpose, and also give the necessary powers to municipalities. It was decided to hold another meeting this week. The members of the Liaison Committee are Sir David Wallace, F.R.C.S., Colonel D. J. Macintosh, Mr. James Macfarlane, Major-General James Thomson, Mr. C. F. Henderson, and Mr. James Thomson. Dr. Elliot intimated that the Secretary of State for Scotland had appointed Mr. Niven F. M'Nicol as secretary of the committee.

Pneumonia Epidemic in Scotland.

An outbreak of pneumonia, which attained considerable proportions, has occurred in Glasgow and other parts of Scotland. At the opening of the week beginning January 13th there were 600 cases of pneumonia in Glasgow hospitals, and on January 14th there were applications for the admission of about 100 others. It is believed that many cases of pneumonia have been contracted by persons suffering from mild attacks of influenza who have returned to work too soon. The total number of deaths in the city in the week ended January 12th was 645, as against 388 in the preceding week; this gives a death rate of 31.2 per 1,000 of population per annum, against 19.5 in the previous week. Deaths from pneumonia numbered 118, including 40 children under 5. The staffs in large businesses appear to have been seriously depleted by the occurrence of influenza, bronchitis, and pneumonia; about 30 per cent. of the tramway workers were on the sick list, and the service was maintained with difficulty, whilst in the Post Office some 10 per cent. of the employees were absent. In the whole of Scotland during the week ended January 12th there were 1,164 deaths, giving a corrected death rate of 24.1 per 1,000; this rate is 6.8 above the average. Relatively high death rates were also recorded in Greenock (34.3), Paisley (23.5), Dundee (19.6), and Kilmarnock (26.1). In Edinburgh the death rate was 17.1, and in Aberdeen 16.7. Deaths from influenza numbered 56, and of these 50 occurred in Glasgow.

Cupar Hospital Extension.

The Adamson Cottage Hospital at Cupar has recently been extended through a gift of £5,000 to the trustees by Mr. and Mrs. J. B. Crichton, Luthriebank, who have also presented an annual income of £1,500 for the next seven years. The hospital was reopened on January 14th by Lord Cochrane of Cults, who said that the hospital was unique in the conveniences it offered amongst the cottage hospitals of the country. In referring to the King's illness, in which great advantages of skilled medical advice and devoted nursing had been available, Lord Cochrane remarked that a hospital equipped like the Adamson Hospital would bring similar advantages within the reach of all in the district who were suffering severely. The additions to the hospital consisted of an operating theatre, *x*-ray and electrical departments, private male and female wards, and waiting and dining rooms.

Edinburgh Royal Maternity Hospital.

At the monthly meeting of the board of directors of the Edinburgh Royal Maternity and Simpson Memorial Hospital, held on January 16th, reference was made to the retirement on the age limit of Dr. William Fordyce, who had been physician to the hospital for the past twenty-seven years. To mark their appreciation of his services the directors appointed Dr. Fordyce as consultant obstetrician to the hospital. At the same meeting Dr. Douglas Miller, who for some years has been assistant physician and registrar to the hospital, was elected as physician to fill the vacancy caused by the retirement of Dr. Fordyce.

England and Wales.

Society of British Neurological Surgeons.

THE fifth meeting of the Society of British Neurological Surgeons was held in London last month under the presidency of Sir Percy Sargent. A visit was paid to Guy's Hospital, where Mr. Lancelot Bromley operated, turning an osteoplastic flap by de Martel's method. The society was addressed by Dr. Hurst on "The cause of trophic disturbances in nerve injuries," and Dr. C. P. Symonds showed cases, including radiograms of a calcified angioma of the brain, to which Mr. Bathe Rawling was able to exhibit a parallel. Dr. Symonds further exhibited a case illustrating tonic innervation of the hand in a young woman, clinically diagnosed as a congenital aneurysm, and a case of cervical rib with cerebral embolism. The relationship between vessel compression and embolism was discussed. Mr. Bromley presented a female patient from whom he had enucleated a spinal tumour; persistent contractures of the hamstrings had necessitated tenotomies, so successfully carried out by Mr. Trethowen that the patient was now able to walk up and down stairs. At the resumed meeting, held in the afternoon at the National Hospital, Queen Square, Sir Percy Sargent opened a discussion on the radium treatment of cerebral tumours, and Mr. Ross described the technique and results so far obtained in a small group operated upon at St. Bartholomew's Hospital. This subject, theoretically so full of promise for the glioma patient, was fully discussed by other members of the society. Dr. Greenfield read a paper on the "Haemangiomatous cysts of the cerebellum (Lindan's tumour)," illustrated by a series of cases in which the pathology of the condition was built up step by step. Other papers read were Professor Archibald Young's on "Chordoma," Mr. Julian Taylor's, advocating a more posterior approach than by the classical London method to the root of the Gasserian ganglion, Mr. A. A. McConnell's

on "Mistakes in the interpretation of ventriculograms," and Mr. Lambert Rogers's on "Elephantiasis neuro-fibromatosa." The society's dinner was held at the Langham Hotel, with Mr. Donald Armour in the chair. On the following morning Mr. L. R. Broster divided the sensory root of the trigeminal nerve for neuralgia, and showed a number of patients, including a young woman with a suprarenal tumour and virility (the second example of this unusual condition which he has placed before the society). Dr. Adie read a brief paper describing cases of spinal and pituitary tumours, and emphasized the importance of being on the watch for these latter in cases of non-syphilitic optic atrophy. Dr. A. B. Rosher contributed a talk on the chemistry and cytology of cerebro-spinal fluid. Dr. Viner discussed the histology of the gliomas, and showed a number of specimens.

Welsh National Memorial Association and the Local Government Bill.

The Minister of Health, accompanied by Sir Kingsley Wood, on January 21st received a deputation from the Welsh National Memorial Association; the deputation was introduced by Colonel David Davies, M.P., president of the association, and included Sir L. Forestier-Walker, M.P., Dr. D. Rocyn Jones, Dr. W. E. Thomas, and Dr. J. H. Williams, M.P. The deputation pointed out that under the Local Government Bill grants towards health services would in the future be included in the general block grants to local authorities, stating that they were anxious that the bill should specifically provide that the Welsh local authorities should continue to contribute out of the block grants towards the work of the association. In particular, the deputation urged that in calculating the loss of grants for the purpose of arriving at the Exchequer contributions payable to the Welsh authorities regard should be had to the capital expenditure incurred by the association out of its own funds, in respect of the provision of hospitals and sanatoriums. The Minister replied that the position of the association would be fully safeguarded by the scheme provided for in the bill, which would prescribe the contributions payable to the association by the local authorities. He intimated that he intended to move a new clause to enable the Minister, on the application of the authorities concerned, to make, on behalf of and at the charge of local authorities, a direct payment to voluntary associations such as the Welsh National Memorial Association of the contributions payable under the scheme. He promised also to insert a provision designed to remove existing difficulties as to the raising of loans which would facilitate the proposed extension of hospital accommodation in Wales. Finally, he undertook to propose a concession under which the grant of one-third of the capital expenditure payable for the standard year would be taken into consideration in calculating the losses on account of grants for the purpose of the general Exchequer contribution under the bill.

Midwifery in London: Criticisms by L.C.C. Committee.

A report was presented to the London County Council on January 22nd setting forth the evidence which it is proposed to give on behalf of the Council to the Departmental Committee (under Sir Robert Bolam's chairmanship) on the training and supply of midwives. The report sets out the position of midwifery in London during the last ten years (here we reproduce only the figures for each third year).

Year.	Total No. of births (exclusive of stillbirths).	Estimated No. of births attended by midwives.	No. of midwives notifying intention to practise in London.
1918	70,976	34,976	535
1921	59,839	46,000	758
1924	85,147	42,000	906
1927	73,203	34,000	870

The Midwives Acts Committee of the Council states that while a rule of the Central Midwives Board requires that candidates for examination must have witnessed not fewer than ten labours, and in addition have attended and watched the progress of not fewer than twenty labours, it is doubtful whether this rule is strictly complied with, as pupil midwives are often moved from one case to another, which prevents their having sufficient opportunities to see a case in all its stages. Institutions which teach midwifery, says the report, should be so staffed that they do not depend upon the work of the pupils, and are not compelled to arrange the work in order to get it done most easily, rather than to the best advantage of the pupils. The ideal to be aimed at should be the teaching and training of the pupil midwife at institutions adequately staffed at which the whole course of training, intern and extern, can be given. The committee has found some midwives apt to leave certain duties concerning both mother and child to handywomen, who may also be employed in the respective cases. Many midwives are extremely ignorant of the matters referred to in the footnote to Rule C 5 of the Board, regarding a knowledge of ophthalmia neonatorum, puerperal fever, and venereal diseases, among other matters, and the committee suggests that this be included in the rule itself and made compulsorily. Again, many midwives, not trained nurses, do not realize the importance of, and cannot even recognize, such conditions as general illness, impending collapse, cyanosis, urinary abnormalities, symptoms of lung disease, and so forth; they have insufficient knowledge of anatomy and of the theory and technique of sepsis and asepsis. The proposed evidence also deals with the qualifications for teachers in midwifery (who should be either medical practitioners with special experience in obstetrics, or fully trained nurses holding the Central Midwives Board certificate and with definite experience of practical midwifery), and, again, with post-certificate courses, which, the committee thinks, should be made compulsory on all practising midwives at intervals of four or five years. The report adds some information regarding midwifery practice in London. In East London the average fee for primiparae is between 25s. and 30s., and for multiparae between 16s. and 21s. The corresponding fees in West London are between 42s. and 50s., and between 30s. and 35s. respectively. With regard to the training of medical students in midwifery, the Midwives Acts Committee cannot regard as satisfactory the extern practice at some hospitals. Sometimes the student goes to a case unaccompanied, and in others the students' cases are nursed by handywomen. It is regarded as essential that medical students shall see only the best midwifery nursing, and shall be accompanied at their cases only by certified midwives with a good standard of work. The proposed evidence goes on to deal with the powers and duties of the Central Midwives Board. The procedure of the Board, it is considered, in connexion with the hearing of prima facie cases of malpractice, negligence, or misconduct on the part of the certified midwife submitted to the Board by the local supervising authority is in need of revision. The normal procedure should be for the prosecution of such midwives to be conducted by the legal representative of the local authority, and power should be given to the Board to enable it to compel the attendance of witnesses and to take evidence on oath. It is also thought that the constitution of the Board should be amended so as to provide for the election of a smaller number of members than at present, and for the inclusion of a member possessing legal training. Another suggestion is that the administrative duties of the Central Midwives Board in connexion with the approval of training centres and of midwives or other persons desirous of undertaking the training of pupil midwives should be transferred to the Ministry of Health, which should have the assistance of an advisory committee representative of local supervising authorities, medical practitioners, and certified midwives.

North of England Dermatological Society.

At a meeting of representative dermatologists from Leeds, Liverpool, Manchester, and Sheffield, held in Manchester on January 15th, it was decided to expand the Manchester Dermatological Society into a North of England Dermatological Society. The society, in addition to the annual general meeting, will hold four clinical meetings a year, one in Liverpool, one in Sheffield, and two in Manchester. The following offices were elected: President, Dr. Saratard (Manchester); vice-presidents, Dr. R. W. McKenna (Liver-

pool), and Dr. Hallam (Sheffield); secretary, Dr. Mumford (Manchester); members of council, Dr. Ingram (Leeds), Dr. Dyson (Manchester), and Dr. Lancashire (Manchester). Any dermatologists (other than those already notified) in the North of England who would like to join are asked to write to the secretary, Dr. P. B. Mumford, 96, Mosley Street, Manchester.

Reconstruction of the Middlesex Hospital.

The work of rebuilding the Middlesex Hospital continues steadily. In the annual report for 1927, presented to the court of governors early in 1928 and now issued, the part of the development scheme dealing with the new nurses' hostel is described in some detail. In the old hospital nurses were housed in five different buildings, but, thanks to the magnificent generosity of an anonymous benefactor, the sum of £160,000 has been given for the erection of a hostel on an adjoining site to provide sleeping, refectory, and recreation accommodation for 180 nurses. The gift was inspired by the good offices of Mr. A. E. Webb-Johnson, surgeon to the hospital and treasurer of the medical school, who has, since the war, raised by his own personal efforts a sum of over £300,000 for the hospital, for the medical school, and for medical education and research. The remainder of the report contains the customary statistical summaries, which show that the number of in-patients during 1927 was increased by 193 over that in 1926 to a total of 5,476; the out-patient figures again expanded substantially, new patients reaching a total of 49,018, the total attendances being 218,260. The average cost of patients was diminished, partly as a result of the increased numbers; the weekly in-patient cost was approximately £4 16s. instead of over £5, and the actual expenditure of the hospital decreased by nearly £1,000 in comparison with that of 1926. The new west wing is rising fast, and the beginnings of the reconstructed hospital are now sufficiently definite to indicate something of the magnitude of the responsibilities with which its board will be confronted, and of the task which has been faced during the period of planning.

Lady Chichester Hospital, Hove.

The emphasis now generally laid on the value of suitable and specialized treatment of early nervous disorder and borderline mental cases finds expression in the activities of the Lady Chichester Hospital (Hove), founded in 1905 for poor women suffering from early nervous breakdown. In the report for the year 1927 it is stated that a large proportion of the patients treated at this hospital make a satisfactory recovery. The treatment adopted is catholic in its scope. At present, rest, fresh air, and generous diet form the basis of treatment on the physical side. A sun-cure court and ultra-violet ray apparatus are being added in the course of the year. Stress is laid on the importance of occupation and amusements, which exercise their therapeutic effect by reawakening objective interests in patients otherwise preoccupied with their own symptoms. When such patients, for example, develop a special capacity for hand-loom weaving, or spinning, or gardening, or are prepared to enter into the spirit of a fancy-dress dance, they have made a definite advance towards cure. Every patient is thoroughly examined on admission, and wherever possible treatment is directed to the removal of any physical disability from which she may be suffering. Habitual constipation, dyspepsia, pyorrhoea, and any septic focus in the tonsils, nasopharynx, ear, or elsewhere, are appropriately dealt with. Physiotherapy—including massage, hydrotherapy, electrical treatment, and remedial exercises—is prescribed in suitable cases. Some patients derive benefit from organotherapy. The psychological methods of treatment include simple suggestion, persuasion, re-education, and mental analysis, and in each case a constructive effort is made to help the patient to redirect her mental energies into socially useful channels. The treatment adopted for any patient is based on a long and sympathetic study of her individual characteristics and preferences, and every attempt is made to avoid the rut of routine methods. Accommodation is provided for fifty-three in-patients, and there were 1,778 attendances at the out-patient department during the past year. The hospital has educational as well as curative activities, and provides tuition for nurses desirous of specializing in the care of patients suffering from early nervous and mental disease.

India.

Public Health Problems in India.

THE annual report of the Public Health Commissioner with the Government of India for 1926 has recently been published in two volumes, the second being devoted to the health of the European and Indian forces and of the jail population, while the first deals with health conditions in their more general aspects. The report has been based upon the vital statistics of the country, supplemented by information from administrative medical officers, directors of public health, medical officers of health, and others in close touch with the medical situation in the provinces, and from officers engaged upon special surveys or inquiries on various diseases. It should be remembered that since the inception of the Montagu-Chelmsford reforms the subject of public health has been under the sway of the provincial Governments, and conditions in regard to public health—as in almost every side of life—vary widely from one part of the subcontinent to another. The central Government has little direct influence in the development of health services, and there is consequently no uniform standard and no co-ordinated policy applicable to British India as a whole. In view of these points, and also of the fact that many of the topics dealt with in the report having already been touched upon in these columns, perhaps the main general interest in the report lies in the views expressed on certain broad questions relating to public health in India.

The summary embodied in the report, and bearing the signature of Lieut.-Colonel F. P. Mackie—who completed the report as officiating public health commissioner in the absence on leave of Colonel J. D. Graham—calls attention to the distressingly high level of infantile mortality. In 1926 India's death rate was $2\frac{1}{3}$ times, and her infantile mortality rate $2\frac{2}{3}$ times, those of England and Wales, and generally an Indian's expectation of life at birth is less than half the average figure for a European. In several towns in 1926 approximately half the infants born died within the first year of life. Such figures as are available respecting the medical examination of school children show that a very high proportion (about two-thirds of those inspected in Bombay) were either diseased or defective; malnutrition was the most prevalent condition, and this, with other evidence, suggests that many of the children were suffering from deficiencies in diet. Colonel Mackie notes also the ill effects of certain social customs, the abolition of which he associates with health education, and the arousing of a public health conscience and a sense of civic responsibility as the preliminary steps of a public health policy. In this connexion mention is made of the publicity work carried on in several provinces with excellent results; a note on the development of health propaganda in Madras was published in the *Journal* of January 5th (p. 34).

A striking illustration of the nature of the problems confronting Indian health administrators is given in the course of a note on the prevalence of cholera, which is essentially a water-borne disease, its prevention being a question of the provision and use of pure water supplies. In one province the attention of the board of health was invited to a recommendation that at least one pakka well for the supply of drinking water should be built in each village; it was found that with the funds available for this purpose 600 years would be required for the execution of the programme. The chief measures employed against plague, which caused about 196,000 deaths in British India in 1926, are mass inoculation and rat destruction; a scheme for the thorough "de-ratting" of villages which was put into operation in the Punjab, where outbreaks were forecast, in the pre-epidemic period

on "Mistakes in the interpretation of ventriculograms," and Mr. Lambert Rogers's on "Elephantiasis neuro-fibromatosa." The society's dinner was held at the Lansdowne Hotel, with Mr. Donald Armour in the chair. On the following morning Mr. L. R. Broster divided the sensory root of the trigeminal nerve for neuralgia, and showed a number of patients, including a young woman with a suprarenal tumour and virility (the second example of this unusual condition which he has placed before the society). Dr. Adie read a brief paper describing cases of spinal and pituitary tumours, and emphasized the importance of being on the watch for these latter in cases of non-syphilitic optic atrophy. Dr. A. B. Rosher contributed a talk on the chemistry and cytology of cerebro-spinal fluid. Dr. Viner discussed the histology of the gliomas, and showed a number of specimens.

Welsh National Memorial Association and the Local Government Bill.

The Minister of Health, accompanied by Sir Kingsley Wood, on January 21st received a deputation from the Welsh National Memorial Association; the deputation was introduced by Colonel David Davies, M.P., president of the association, and included Sir L. Forestier-Walker, M.P., Dr. D. Rocyn Jones, Dr. W. E. Thomas, and Dr. J. H. Williams, M.P. The deputation pointed out that under the Local Government Bill grants towards health services would in the future be included in the general block grants to local authorities, stating that they were anxious that the bill should specifically provide that the Welsh local authorities should continue to contribute out of the block grants towards the work of the association. In particular, the deputation urged that in calculating the loss of grants for the purpose of arriving at the Exchequer contributions payable to the Welsh authorities regard should be had to the capital expenditure incurred by the association out of its own funds, in respect of the provision of hospitals and sanatoriums. The Minister replied that the position of the association would be fully safeguarded by the scheme provided for in the bill, which would prescribe the contributions payable to the association by the local authorities. He intimated that he intended to move a new clause to enable the Minister, on the application of the authorities concerned, to make, on behalf of and at the charge of local authorities, a direct payment to voluntary associations such as the Welsh National Memorial Association of the contributions payable under the scheme. He promised also to insert a provision designed to remove existing difficulties as to the raising of loans which would facilitate the proposed extension of hospital accommodation in Wales. Finally, he undertook to propose a concession under which the grant of one-third of the capital expenditure payable for the standard year would be taken into consideration in calculating the losses on account of grants for the purpose of the general Exchequer contribution under the bill.

Midwifery in London: Criticisms by L.C.C. Committee.

A report was presented to the London County Council on January 22nd setting forth the evidence which it is proposed to give on behalf of the Council to the Departmental Committee (under Sir Robert Bolam's chairmanship) on the training and supply of midwives. The report sets out the position of midwifery in London during the last ten years (here we reproduce only the figures for each third year).

Year.	Total No. of births (exclusive of stillbirths).	Estimated No. of births attended by midwives.	No. of midwives notifying intention to practise in London.
1918	70,976	34,976	535
1921	89,839	46,000	758
1924	85,147	42,000	906
1927	73,203	34,000	870

The Midwives Acts Committee of the Council states that while a rule of the Central Midwives Board requires that candidates for examination must have witnessed not fewer than ten labours, and in addition have attended and watched the progress of not fewer than twenty labours, it is doubtful whether this rule is strictly complied with, as pupil midwives are often moved from one case to another, which prevents their having sufficient opportunities to see a case in all its stages. Institutions which teach midwifery, says the report, should be so staffed that they do not depend upon the work of the pupils, and are not compelled to arrange the work in order to get it done most easily, rather than to the best advantage of the pupils. The ideal to be aimed at should be the teaching and training of the pupil midwife at institutions adequately staffed at which the whole course of training, intern and extern, can be given. The committee has found some midwives apt to leave certain duties concerning both mother and child to handywomen, who may also be employed in the respective cases. Many midwives are extremely ignorant of the matters referred to in the footnote to Rule C 5 of the Board, regarding a knowledge of ophthalmia neonatorum, puerperal fever, and venereal diseases, among other matters, and the committee suggests that this be included in the rule itself and made compulsorily. Again, many midwives, not trained nurses, do not realize the importance of, and cannot even recognize, such conditions as general illness, impending collapse, cyanosis, urinary abnormalities, symptoms of lung disease, and so forth; they have insufficient knowledge of anatomy and of the theory and technique of sepsis and asepsis. The proposed evidence also deals with the qualifications for teachers in midwifery (who should be either medical practitioners with special experience in obstetrics, or fully trained nurses holding the Central Midwives Board certificate and with definite experience of practical midwifery), and, again, with post-certificate courses, which, the committee thinks, should be made compulsory on all practising midwives at intervals of four or five years. The report adds some information regarding midwifery practice in London. In East London the average fee for primiparae is between 25s. and 30s., and for multiparae between 16s. and 21s. The corresponding fees in West London are between 42s. and 50s., and between 30s. and 35s. respectively. With regard to the training of medical students in midwifery, the Midwives Acts Committee cannot regard as satisfactory the extern practice at some hospitals. Sometimes the student goes to a case unaccompanied, and in others the students' cases are nursed by handywomen. It is regarded as essential that medical students shall see only the best midwifery nursing, and shall be accompanied at their cases only by certified midwives with a good standard of work. The proposed evidence goes on to deal with the powers and duties of the Central Midwives Board. The procedure of the Board, it is considered, in connexion with the hearing of prima facie cases of malpractice, negligence, or misconduct on the part of the certified midwife submitted to the Board by the local supervising authority is in need of revision. The normal procedure should be for the prosecution of such midwives to be conducted by the legal representative of the local authority, and power should be given to the Board to enable it to compel the attendance of witnesses and to take evidence on oath. It is also thought that the constitution of the Board should be amended so as to provide for the election of a smaller number of members than at present, and for the inclusion of a member possessing legal training. Another suggestion is that the administrative duties of the Central Midwives Board in connexion with the approval of training centres and of midwives or other persons desirous of undertaking the training of pupil midwives should be transferred to the Ministry of Health, which should have the assistance of an advisory committee representative of local supervising authorities, medical practitioners, and certified midwives.

North of England Dermatological Society.

At a meeting of representative dermatologists from Leeds, Liverpool, Manchester, and Sheffield, held in Manchester on January 15th, it was decided to expand the Manchester Dermatological Society into a North of England Dermatological Society. The society, in addition to the annual general meeting, will hold four clinical meetings a year, one in Liverpool, one in Sheffield, and two in Manchester. The following offices were elected: President, Dr. Sarafard (Manchester); vice-presidents, Dr. R. W. McKenna (Liver-

pool), and Dr. Hallam (Sheffield); secretary, Dr. Mumford (Manchester); members of council, Dr. Ingram (Leeds), Dr. Dyson (Manchester), and Dr. Lancashire (Manchester). Any dermatologists (other than those already notified) in the North of England who would like to join are asked to write to the secretary, Dr. P. B. Mumford, 96, Mosley Street, Manchester.

Reconstruction of the Middlesex Hospital.

The work of rebuilding the Middlesex Hospital continues steadily. In the annual report for 1927, presented to the court of governors early in 1928 and now issued, the part of the development scheme dealing with the new nurses' hostel is described in some detail. In the old hospital nurses were housed in five different buildings, but, thanks to the magnificent generosity of an anonymous benefactor, the sum of £160,000 has been given for the erection of a hostel on an adjoining site to provide sleeping, refectory, and recreation accommodation for 180 nurses. The gift was inspired by the good offices of Mr. A. E. Webb-Johnson, surgeon to the hospital and treasurer of the medical school, who has, since the war, raised by his own personal efforts a sum of over £300,000 for the hospital, for the medical school, and for medical education and research. The remainder of the report contains the customary statistical summaries, which show that the number of in-patients during 1927 was increased by 193 over that in 1926 to a total of 5,476; the out-patient figures again expanded substantially, new patients reaching a total of 49,018, the total attendances being 218,360. The average cost of patients was diminished, partly as a result of the increased numbers; the weekly in-patient cost was approximately £4 16s. instead of over £5, and the actual expenditure of the hospital decreased by nearly £1,000 in comparison with that of 1926. The new west wing is rising fast, and the beginnings of the reconstructed hospital are now sufficiently definite to indicate something of the magnitude of the responsibilities with which its board will be confronted, and of the task which has been faced during the period of planning.

Lady Chichester Hospital, Hove.

The emphasis now generally laid on the value of suitable and specialized treatment of early nervous disorder and borderline mental cases finds expression in the activities of the Lady Chichester Hospital (Hove), founded in 1905 for poor women suffering from early nervous breakdown. In the report for the year 1927 it is stated that a large proportion of the patients treated at this hospital make a satisfactory recovery. The treatment adopted is catholic in its scope. Public Health Problems in India.

THE annual report of the Public Health Commissioner with the Government of India for 1926 has recently been published in two volumes, the second being devoted to the health of the European and Indian forces and of the jail population, while the first deals with health conditions in their more general aspects. The report has been based upon the vital statistics of the country, supplemented by information from administrative medical officers, directors of public health, medical officers of health, and others in close touch with the medical situation in the provinces, and from officers engaged upon special surveys or inquiries on various diseases. It should be remembered that since the inception of the Montagu-Chelmsford reforms the subject of public health has been under the sway of the provincial Governments, and conditions in regard to public health—as in almost every side of life—vary widely from one part of the subcontinent to another. The central Government has little direct influence in the development of health services, and there is consequently no uniform standard and no co-ordinated policy applicable to British India as a whole. In view of these points, and also of the fact that many of the topics dealt with in the report having already been touched upon in these columns, perhaps the main general interest in the report lies in the views expressed on certain broad questions relating to public health in India.

The summary embodied in the report, and bearing the signature of Lieut.-Colonel F. P. Mackie—who completed the report as officiating public health commissioner in the absence on leave of Colonel J. D. Graham—calls attention to the distressingly high level of infantile mortality. In 1926 India's death rate was $2\frac{1}{4}$ times, and her infantile mortality rate $2\frac{3}{4}$ times, those of England and Wales, and generally an Indian's expectation of life at birth is less than half the average figure for a European. In several towns in 1926 approximately half the infants born died within the first year of life. Such figures as are available respecting the medical examination of school children show that a very high proportion (about two-thirds of those inspected in Bombay) were either diseased or defective; malnutrition was the most prevalent condition, and this, with other evidence, suggests that many of the children were suffering from deficiencies in diet. Colonel Mackie notes also the ill effects of certain social customs, the abolition of which he associates with health education, and the arousing of a public health conscience and a sense of civic responsibility as the preliminary steps of a public health policy. In this connexion mention is made of the publicity work carried on in several provinces with excellent results: a note on the development of health propaganda in Madras was published in the *Journal* of January 5th (p. 34).

A striking illustration of the nature of the problems confronting Indian health administrators is given in the course of a note on the prevalence of cholera, which is essentially a water-borne disease, its prevention being a question of the provision and use of pure water supplies. In one province the attention of the board of health was invited to a recommendation that at least one pakka well for the supply of drinking water should be built in each village; it was found that with the funds available for this purpose 600 years would be required for the execution of the programme. The chief measures employed against plague, which caused about 196,000 deaths in British India in 1926, are mass inoculation and rat destruction; a scheme for the thorough "de-ratting" of villages which was put into operation in the Punjab, where outbreaks were forecast, in the pre-epidemic period

is stated to have met with "phenomenal success." In connexion with malaria, the most important preventable disease in India, the suggestion is made that possibly the main hope of salvation lies in steady improvement of the general health, which will increase the resistance to the disease. The importance of nutritional research is emphasized. It will be noted that, in the case of the three diseases mentioned, the problems they present are financial and administrative rather than purely medical; in the words of the report:

"The knowledge is there, but the means or the will to apply it are lacking." Colonel Mackie, expanding this theme, states that in the case of five of the principal diseases of India—malaria, plague, small-pox, cholera, and kala-azar—the natural history of the disease has been sufficiently elucidated "to enable preventive medicine to stamp them out if only money, energy, and co-operation were combined in one grand attack."

Too much praise cannot be given to the various research agencies who have made such a statement possible.

After paying a tribute to the work of the leading voluntary organizations, and referring to the importance of public co-operation in public health, the summary concludes with a note on certain administrative problems which are the consequence of the reforms. Mention has already been made of the fact that under the diarchal system the provinces are practically autonomous in the sphere of public health. It is urged that some central co-ordinating and advisory body on the lines of a Ministry of Health is necessary to organize, among other things, the control of epidemics, and to establish a definite standard in health services for the provinces. Occasion is taken to direct attention to the importance of preventive, as compared with curative, medicine. In conclusion, a plea is put forward for the provision of adequate facilities for training in public health work under Indian conditions, in view of the fact that this is being more and more handed over to Indians. Colonel Mackie writes:

"It is our duty when the time comes to hand over the government of the country to its own sons to see that we leave it with a strong, well organized, and efficient public health service; and that is, I believe, the greatest boon which Western medical science can confer upon India."

Prince of Wales Medical College, Patna.

The annual report of the Prince of Wales Medical College, Patna, for the year 1927–28 is of special interest in view of the fact that that institution is of recent foundation, and is endeavouring to raise its standard in the hope of securing recognition for its degrees from the General Medical Council. The college commenced its third session in July, 1927, with 195 students on the rolls, including 41 new entrants. Applications for admission numbered 82, against 183 and 270 in the two previous years, and the principal, Lieut.-Colonel H. R. Dutton, fears that a further decrease may make it difficult to maintain a satisfactory standard of quality in the students. In the course of the year the first group of regular students, who commenced work in 1925, reached Part II of the second M.B., B.S. examination, which only 12 of the original 31 succeeded in passing. At the end of the year the new extension of the department of physiology was almost complete, and work on various other buildings had made considerable progress. Nothing had been done, however, towards the foundation of the proposed new public health laboratory. Important additions have been made to the equipment of several departments, but the library is deficient in books of reference and in files of medical and scientific journals. Despite the difficulties inseparable from the early years of a new institution of this kind, research work has been started in all departments.

Provincialization of Medical Services in the Punjab.

The tendency in most of the provinces of India in recent years has been definitely towards the substitution of a provincial health service comprising the health officers employed in the districts for the system under which such officers were employed by the individual district boards. In a number of provinces this change is being carried out gradually, and in the Punjab the scheme for provincializing the service of district medical officers of health, which received administrative sanction in 1926, came into force on April 1st, 1927. In his annual report for that year the director of public health, Lieut.-Colonel C. A. Gill, states that the cadre comprises 37 appointments: 28 are district officers, 3 assistant epidemiologists, 2 are held in reserve for emergencies, and the remaining 4 officers constitute a leave reserve. The existing incumbents of provincial and district board appointments were posted to 21 districts, and 6 additional appointments were made during the year, leaving only one district (excluding Simla) without a whole-time medical officer of health holding a diploma of public health. Three of the reserve posts have also been filled, but the auxiliary staff originally sanctioned for district work has been considerably curtailed, so that it was only possible to provide each district with one sanitary inspector and one dispenser, the remainder—including 24 sub-assistant surgeons and 19 sanitary inspectors—being engaged on a temporary basis for combating epidemics. One of the most urgent needs noted in the report is the provision of whole-time or part-time medical officers of health in the towns. Whole-time municipal medical officers of health were employed in nine towns, and three other large towns agreed to do so on condition that half the cost of the salaries was met by the Government.

Correspondence.

HEART SOUNDS.

SIR,—Dr. T. Stacey Wilson says, very rightly, when criticizing my letter on heart sounds (January 5th, p. 43): "I feel that a word of physiological protest must be uttered with regard to his suggestion that, in spite of the absence of valves or adequate sphincter muscles, the auricle can develop a force comparable with that of the ventricle."

I do not think that I have ever maintained that the auricle can exert such a "force." I maintain that it can, theoretically, exert such a *pressure*. With a Bramah press a small force can exert a pressure which can overcome a much greater force, and when the auricle, by contracting, becomes small, it has only a small internal area of resistance to oppose its contraction; whereas, should the ventricle begin to contract against it, supposing their contractions at any time to overlap, the ventricle would have a large internal area of resistance to oppose its contraction. For this reason chiefly, but also from the advantage a decreasing chamber has in piling up its muscles, if the mitral valve were stenosed the auricle could, theoretically, drive the residue of its blood into the ventricle. Could it do this practically? All depends, as Dr. Wilson suggests, on whether the sphincter at the great veins be adequate. Now the cardiac cycle begins at these great veins and spreads to the auricle. An effort is therefore made to prevent regurgitation. Is it adequate?

The cardiac contraction is a masked peristalsis, consequent on the mode of development of the heart from a tube. Starting at the great veins the auricle urges the blood away from them during its contraction. Roy and Adami[1] have shown how the pressure rises in the auricles, and how unlike a passive or "simple reservoir" the auricle is.

In mitral stenosis the left auricle hypertrophies (it is commonly taught that it dilates and hypertrophies, but I have shown, by examining the records of all cases of death with stenosis during ten years at Guy's Hospital, that *hypertrophy* is the characteristic change[2]), and sometimes approximates to a ventricle by the extent of its hypertrophy.

It is scarcely conceivable that a "simple reservoir," as Dr. Stacey Wilson says, approvingly, Dr. Mayo Collier considered the auricle to be, can have any purpose in hypertrophying. It would be less useful than before. The hypertrophy, on the other hand, of a contracting auricle which propels blood onwards is clearly advantageous, provided it does not leak backwards. Should it so leak it would accelerate death, which is obviously not its role.

[1] *Practitioner*, vol. 44, p. 170.
[2] *British Medical Journal*, February 5th, 1893

It hypertrophies to help, and gets the blood through the stenosed orifice for years. The sphincters at the great veins is adequate in practice; and sphincters are as good as valves, or we should have no birds.

The main purpose of my various communications on this subject has been to indicate the theoretical possibilities of the auricle, and to remove the impression that because the ventricle is thicker and has more muscle than the auricle it must necessarily overcome it. On equal terms it would do so, but the auricle scores by contracting first and becoming small. If the sphincters at the great veins be adequate, as I maintained in my letter on the genesis of the venous pulse,[1] the auricle should be more than a match for the ventricle, should their contractions overlap, as occurs apparently in many cases of mitral stenosis.—I am, etc.,

Mentone, Jan. 11th. D. W. SAMWAYS.

THE DICK TEST IN SCARLET FEVER.

SIR,—The article by Dr. William Brown on the Dick test in scarlet fever (*British Medical Journal*, January 5th, p. 13) confirms some of the work published by Dr. A. H. G. Burton and myself last year ("Relapses in scarlet fever," *Lancet*, May 26th), in particular, the effect of scarlatinal antitoxic serum in increasing the number of Dick-positive reactors during convalescence, and therefore the greater possibility of relapses and second attacks in serum-treated cases.

Dr. Brown does not state the size of the Dick reaction he obtained in his cases nor the area of erythema he accepted as a minimum for a Dick-positive result to be recorded, hence it is difficult to compare his work with that of other investigators. He refers to the disparity between his results in the first few days of the disease and those of Zingher, and suggests that it may be due to the toxin used. In the article above referred to we pointed out that the reason for Zingher's high percentage of positive reactors was that he included all grades of reaction. One cannot agree with Dr. Brown when he says "that it is impossible to state that the positive Dick test does indicate a lack of immunity to scarlet fever," and he gives no evidence for this statement, while the body of evidence against it is very considerable. Further, he contradicts himself when, with regard to the eight Dick-positive reactors out of his seventy-six serum-treated cases, he states that, "these eight patients had not developed their antitoxic immunity." Also when he says that of eighty-three patients "the Dick test was negative, thus indicating that they are no longer susceptible to scarlet fever," he is in direct contradiction to the case he quotes previously of a nurse who was twice found to be Dick-negative and yet developed a typical attack of scarlet fever. It would have been informative if he had stated in this instance how long before the attack the nurse had been Dick-tested. The fact that eighty-three patients were Dick-negative five years after an attack of scarlet fever by no means proves that it was the attack of scarlet fever that caused them to develop immunity.—I am, etc.,

Public Health Offices, Ilford, Jan. 14th. A. R. BALMAIN.

SEQUELS OF HEAD INJURIES.

SIR,—In Dr. C. P. Symonds's paper on cerebral states consequent upon head injuries, published in the *British Medical Journal* on November 10th, 1928, the following statement appears: "It would seem even that a fracture of the skull, if not fatal, may carry with it some degree of immunity from disabling after-effects" (p. 831). This statement is based on the observation that among ten cases of head injury with fracture not one patient was completely disabled, but seven were able to do full work and three light work; whereas in sixty-one cases without fracture the corresponding figures were seven, twenty-six, and twenty-eight respectively.

At first glance the difference between the two sets of figures is sufficiently striking; analysis, however, by the method described in chapter iv of Fisher's *Statistical Methods for Research Workers* leads to the result $P=0.24$, or, expressing this in words, the odds against the occurrence, through the agency of chance alone, of a difference as great as that found, or greater, are about three to one. This falls far below the limit demanded by most statisticians—namely, twenty to one. An illustration will make this clearer. If two cards drawn at random from a pack were found to belong to the same suit, no one would conclude or even suggest that the pack was in any way abnormal; yet the probability of this happening with a normal pack is no greater than the probability that the figures recorded by Dr. Symonds would be obtained if there were no relationship whatever between fracture and the frequency of after-effects.

In these remarks I do not, of course, mean to imply that a rigid statistical backing is required for every tentative suggestion—if this were insisted upon we should get nowhere; I merely wish to point out that Dr. Symonds's findings *can* be accounted for perfectly adequately by chance alone.—I am, etc.,

Pretoria, Dec. 12th, 1928. I. LIEBAITZKY, M.Sc., M.B.

PYORRHOEA ALVEOLARIS.

SIR,—In a paper on pyorrhoea alveolaris by Mr. Humphreys in the *Journal* for January 19th (p. 99), and also in your leader on this subject, it would seem to be taken for granted that the deposition of the "subgingival or soruminal" tartar is the result of the growth of the *Leptothrix buccalis*; yet the fact is noted that this organism is only found in conjunction with this type of tartar, and is absent with the more common salivary variety. No reasons, however, have been brought forward to explain why the leptothrix should flourish in this situation and bring about this specialized tartar in this place. Is it not possible that, given this type of tartar, the circumstances become favourable for the growth of this special organism, and that the leptothrix is the result of the tartar rather than that the tartar is the result of the leptothrix?

In a book recently published by me, and referred to by Mr. Humphreys, I have considered at some length the biochemical changes which would result in such a deposition, and have attempted to show that these upsets are such as might commonly be expected at those periods of life in which pyorrhoea is most usually found. Further, the visualization there presented explains the reasons behind the antagonism between dental caries and pyorrhoea mentioned by Mr. Humphreys, and provides an explanation of the etiology of both conditions dependent upon alterations in the acid-base balance of the blood and the compensatory changes which these will bring about—an explanation which is not necessarily antagonistic to the suggestions of Mrs. Mellanby, but complementary thereto, in that it accounts for many cases of dental caries which cannot be explained on her hypothesis.—I am, etc.,

Bournemouth, Jan. 20th. F. W. BRODERICK.

SIR,—The article by Mr. Humphrey Humphreys on pyorrhoea alveolaris and the editorial comment thereon open up a subject of widespread interest to the medical profession.

In dealing with the causal factors Mr. Humphreys mentions diet, irregular arrangement of the teeth, and dental restoration in their varied forms, all in one way or another favouring stagnation. Besides these I would like to suggest another cause—namely, the commonly used tooth-brush. It seems to me that the extremely prevalent condition of pyorrhoea alveolaris as observed in practice to-day in early adult life, in mouths with otherwise good teeth, must have some other common cause than those enumerated by Mr. Humphreys, and I cannot help thinking that the vigorous use of a hard brush, which is always septic, and frequently filthy, must, by infecting the gums and separating the alveoli from the teeth, help to form those very "pockets" on which so much emphasis is laid.

For some years it has been my custom to recommend these patients, and with satisfactory results, to discard the toothbrush altogether and make the necessary alteration in their diets, particularly an apple with the skin on after a meal; the teeth are then cleaned with an orange stick, that is, the alveolar margin and interdental spaces,

[1] *British Medical Journal*, April 13th, 1912.

and finally the mouth washed out with a hydrogen peroxide wash. The method has, at least, the merit of being hygienic, easy of application, and not requiring any more time than the use of a brush. In my opinion if this practice were more generally adopted we should in time hear less of and see fewer patients with that annoying malady.

Who ever heard of anyone trying to make an article clean by using something dirty, or a surgeon endeavouring to cleanse the skin with a dirty septic nailbrush. Yet that is actually what is being done to-day when endeavouring to cleanse the teeth and gums with a dirty brush. A brush may be all right for dental plates, but not for healthy gums and teeth.—I am, etc.,

London, W.9, Jan. 20th. R. J. MAYBERRY, M.B., Ch.B.

SIR,—At the risk of being dubbed a crank on dead and infected teeth may I enter into the discussion you invite in your leader of January 19th (p. 115) on the effects of pyorrhoea, if any, on health.

How pyorrhoea can affect the general health, provided the gastric secretion be normal, is an enigma to me. Most of the organisms formed must be destroyed in the mouth, unless it is grossly septic; what escape must undergo the same fate in a normal stomach.

Mr. Humphreys's article is admirable and clears up a great deal about pyorrhoea. He rightly attributes most of the diseases of dental origin to dead and infected teeth. I fully endorse his opinion that a negative radiogram means nothing, though a positive one is invaluable. Weston Price goes further, and states that it is just those teeth which present no radiographic evidence of disease which are the worst offenders, since there is no protective granuloma at the apex.

The teeth which occasion constitutional disturbances fall into four main catagories[1]: (*a*) Teeth which have been filled and in which all caries has not been removed; decay proceeds under the filling, and if the filling is intact there is no exit for the pus. (*b*) Teeth in which the pulp was septic at the time of filling and in which root treatment was instituted; a procedure based on very doubtful principles.[2] (*c*) Those in which the pulp has died as the result of some failure of technique and has become infected through the blood stream. (*d*) Root fragments which were septic at the time of the extraction or have become infected autogenously. In all such teeth there is a bead of pus enclosed in rigid walls out of reach of any tissue which can replace it, though occasionally nature deals with it by calcification. Organisms develop in it, being derived from the original caries or from the blood stream. Especially important among these are the anaerobic ones which generate tension by forming gas, so that one can visualize pus being actually squirted into the bone marrow sinusoids, thence entering the blood stream.

In all patients presenting vague or atypical symptoms I make it my practice to examine the teeth. I have almost lost count of the cases of so-called rheumatic disease which have resulted from infected teeth. Among the rarer diseases due to them I have seen recurrent lymphangitis,[3] pyrexia, gleet.[4] An excellent list of such cases was published by Mackey.[5]

At one time I thought that a vital pulp would not transmit infection, but a recent case has made me dubious. The patient had had attacks of fibromyositis, which cleared up for a year after the extraction of an infected dead tooth. He then had a recurrence, though in the slightest possible form; the attacks ceased on having a tooth refilled, the original filling showing decay around it. Is it possible that the patient had been rendered so susceptible by the previous attacks as to be affected by the small amount of toxin liberated by the subsequent caries? The lowering of a patient's immunity to streptococci is well known.

The importance of dead and infected teeth is but now being recognized. That they occur among the educated classes who take scrupulous care of their teeth makes them all the more unsuspected.—I am, etc.,

London, W.1, Jan. 19th. A. P. BERTWISTLE, F.R.C.S.Ed.

TREATMENT OF CANCER BY LEAD.

SIR,—As colleagues of Dr. Todd we feel justified in supporting his contention that Mr. J. Basil Hume wrote his general condemnation of the treatment of cancer by lead from his own experience of particular cases. Dr. Todd, in his letter published last week (p. 130), quoted cases well known to us, and we have seen many others which, in our opinion, justify us in asking Dr. Todd to co-operate with us in treating cancer cases with lead compounds. Relief from pain and sufficient improvement to allow patients to return to work are the usual results. It has not been our experience that the patients were converted into physical wrecks, and we have not been impelled to decline to share the responsibility of continuing the treatment. On the contrary, we have not hesitated to recommend the University of Bristol and the Royal Infirmary to contribute to the maintenance of the research in which Dr. Todd is engaged.—We are, etc.,

J. A. NIXON,
Professor of Medicine in the University of Bristol; Senior Physician to the Bristol Royal Infirmary.

C. FERRIER WALTERS,
Senior Surgeon, Bristol Royal Infirmary.

R. S. STATHAM,
Bristol, Jan. 21st. Gynaecologist to the Bristol Royal Infirmary.

VACCINE TREATMENT OF PUERPERAL SEPSIS.

SIR,—With reference to the paper by Dr. R. R. Armstrong and Mr. W. Shaw, published on December 15th, 1928 (p. 1082), in which they give the results of an investigation to decide the utility of sensitized vaccines in the prophylaxis and treatment of puerperal sepsis, might we suggest the following views to explain the disappointing results of these authors?

In this investigation the authors used a sensitized killed *Streptococcus pyogenes* vaccine. Dr. J. A. Arkwright (December 29th, p. 1193) criticizes the value of sensitized vaccines, "which the authors [Armstrong and Shaw] themselves, in agreement with most other workers, declare to be of very doubtful value." Whether or not sensitized vaccines are a failure, it must be admitted that in the past the results of treatment of puerperal sepsis by vaccines, and even antistreptococcal serums, are varied, and though by no means unfavourable are somewhat disappointing, more especially as most investigators are agreed that puerperal sepsis, especially the graver septicaemic forms, are due to *Streptococcus pyogenes*.

A review of the literature upon the subject of vaccine therapy reveals the fact that the best results were obtained from the use of autogenous streptococcal vaccines. In our opinion the main difficulty is to get the correct type of streptococcus with which to make the vaccine. There are an enormous number of species of streptococci; for example, the *Streptococcus viridans* group consists of at least fifty distinct varieties. The haemolytic group also consists of many types. It was formerly believed that *S. pyogenes* and *S. erysipelatis* were identical. Birkhaug, however, has now proved that *Streptococcus erysipelatis* is a definite specific type. Moreover, treatment in the past of erysipelas by an antiserum prepared from *Streptococcus pyogenes* was more or less a failure. It has been demonstrated, however, that an antistreptococcal serum made from the *Streptococcus erysipelatis* is extremely efficient.

In puerperal fever streptococci have been isolated from the uterine discharges, and several of these have been claimed to be the cause of puerperal fever. The streptococci isolated, however, have not been sufficiently identified. It is not enough to say that the streptococcus is haemolytic, because there are many varieties of haemolytic streptococci. A streptococcal vaccine prepared from such discharges may or may not contain the specific streptococcus, and may therefore fail to give results. In our present state of insufficient knowledge it is a question of

[2] C. Jent ... Dead and Infected Teeth: Ibid, April 28th, 1928.
[3] A. P. ... *Brit. Journ. Surg.*, 1926, p. 295.
[4] A. P. Bertwistle: The ... of Suppurating Pulps on Health, *The Dental Surgeon*, 1928, p. 596.
[5] L. Mackey: Dental Sepsis and Apical Infection, *The British Dental Journal*, September 1st, 1922.

luck whether the vaccine, be it autogenous or stock, really contains the causal organism. A streptococcus isolated in pure culture from the blood of a puerperal fever patient is more likely to be the true causal species.

The number of species of streptococci is enormous, and the identification of the various types is exceedingly difficult and baffling. Many varieties are certain to be obtained from uterine or vaginal discharges. It is not surprising, therefore, that the results of vaccine and anti-streptococcal serum treatment in the past have been disappointing, but this is not the fault of such modes of treatment. The reason of the failure is inability to isolate the proper species of streptococcus.

In our publications on the streptococci[1] we have shown that by the use of Warren Crowe's chocolate agar medium and photomicrography the whole problem of the differentiation of streptococci is rendered much more definite and accurate. We may mention the following examples to illustrate the difficulties and to impress the importance of this medium in differentiating the streptococcal group. Thus Warren Crowe has shown that a broth culture is never representative of the streptococci at the root of a tooth. Certain ones grow out to the exclusion of the others; thus, for example, one tooth extracted produced twelve varieties on his differential medium, whereas only three were found in the broth culture from the scraping of the apex of the tooth. In another case fifteen varieties of streptococci were cultured, and only one organism occurred in the broth. We mention Warren Crowe's medium in order to emphasize its utility as a differential medium for streptococci, as we feel this is not generally well known.—We are, etc.,

D. THOMSON.
R. THOMSON.

London, W.1, Jan. 16th.

THE TEMPERATURE IN PULMONARY TUBERCULOSIS.

SIR,—I am very grateful for the commendation and criticisms of Dr. Vere Pearson on January 12th (p. 80), and also welcome his references, because of the difficulty of finding them in the recent literature.

From 1921 to 1928, while I was medical superintendent of Creaton Sanatorium, I frequently attended meetings of the Society of Medical Superintendents of Tuberculosis Institutions, but I did not hear any discussion on the important subject of temperature. My paper was intended to give hints to beginners in the tuberculosis service and to interested general practitioners rather than to experts.

My contribution was originally entitled "Some points concerning the temperature in pulmonary tuberculosis," because it did not profess to cover the whole subject. It contained some observations on the history of thermometry, and reference was made to the admirable outline of the history contained in Dr. Varrier-Jones's book *The Significance of Temperature Variations in Tuberculous Disease*, but editorial exigencies compelled their withdrawal. In fact, the idea of the "plateau" and "valley" were borrowed from him for quite a different use; for this I hope he will forgive me.

I should like to clear up some of my "ambiguous points." As regards the time necessary for taking temperatures I was thinking more of the time of the overworked nurses rather than that of the patients. I would prefer that a nurse should insert the thermometer for a rectal temperature, in view of the possible risk of accident in a careless insertion by the patient. For the oral temperature, where each patient has his own thermometer, the nurse can go round and read the temperatures in rapid succession. I agree that "there is no such thing as a normal temperature" for all persons, and that is why I suggested that previous records for each patient should be obtained if possible. I had many female patients with a continued premenstrual rise of temperature lasting ten to fourteen days, but a week was about the average. Dr. Pearson takes this "normal" rise as a matter of course, but I could find no mention of it in the literature. The "febrile" premenstrual rise only is noted.—I am, etc.,

COLIN MILNE.

Banbury, Jan. 13th.

[1] *Annals of the Pickett-Thomson Research Laboratory*, vol. iii, et seq.

SIR,—The importance of a close study of the variations of the temperature of the body in pulmonary tuberculosis, especially in its chronic form, cannot be adequately and fully realized until extensive and exhaustive investigations have been made. Obviously Dr. Colin Milne's records and analyses are too sketchy and casual to help those who wish to understand the meaning of the changes of temperature and thereby to help their patients.

I have been studying the temperatures of chronic pulmonary tuberculosis since the discovery of tuberculin, by means of which we may at will produce temperatures of every kind and degree. I even venture to say that those who have not studied the fever phases induced by experiments with tuberculin under many conditions cannot realize the revelation that awaits them in this fascinating study. Of recent years I have taught many physicians to sense the music of a temperature chart as though it were a score of music written by a musical genius, and I would invite Dr. Colin Milne and Dr. Vere Pearson to come and learn for themselves at our institution what temperatures in chronic pulmonary tuberculosis mean, and how to create these entrancing charts for their own delight and the delight of their patients.

I must be candid and tell Dr. Colin Milne that his method of taking temperatures is but a jangle of discords; too many notes in the music are lost. He refers to a number of cases in which the temperatures have all been taken in the same perfunctory way. I fear that he is dealing with material he cannot control and his deductions may be open to criticism. It is not possible to learn much of temperature variations in pulmonary tuberculosis if one takes the temperatures only twice a day. Although Dr. Milne postulates that the temperatures must be determined with exactness he is satisfied with taking temperatures twice daily for three weeks and drawing conclusions thereon.

In my observations over some decades of years I have stipulated that the temperatures must be taken every four hours—even every two hours—and under conditions which are familiar to all my old pupils in Australia and my new pupils in England. Those who have studied with me in England will vouch for the thoroughness and trustworthiness of our method of taking the temperature, and I would invite all who wish to learn the lesson to be read from accurate temperatures taken according to our ideas to spend a few months at the Tuberculin Dispensary, 32, Fitzroy Street, W.1. Here we are producing at will temperatures in pulmonary tuberculosis, which on close study reveal to us some of the mysteries of tuberculosis and its laws of immunity and, still more, enable us to exploit tuberculin—the greatest discovery in medicine of modern times—so as to build up and strengthen the mechanism of immunity and thus give relief and hope of recovery to the myriads of human beings enmeshed in the coils of this insidious and treacherous disease.

When systematic and careful analyses have been carried out in conformity with the general principles I have followed, there will be no more talk of the advantages of rectal temperature records over mouth temperatures. Rectal temperatures, except in children, are as little required in chronic pulmonary tuberculosis as in other febrile conditions.—I am, etc.,

W. CAMAC WILKINSON, M.D.Lond.

London, W.1, Jan. 17th.

AMAUROTIC FAMILY IDIOCY.

SIR,—With reference to Dr. Stenhouse Stewart's article and interesting family tree of amaurotic family idiocy (January 19th, p. 101) I think Mendelism gives the answer to several of his questions. The disease is obviously a recessive characteristic, as otherwise two unaffected parents could not have affected children. It must therefore have occurred on the sides of both the parents (Wolff R. and Annie L.), who are of the Mendelian type DR. Rebecca is also a DR, and Lily, David, Jacob, Pauline, and Rachel are either DR or DD. The disease is such a rare one that the chances of a DR marrying into another tainted family are exceedingly small, hence the rarity of the occurrence in the second generation; nevertheless, this

happened in the case of Rebecca. Is she a cousin or more remotely a relation of her husband?

The answers to the questions are therefore: (1) It is exceedingly unlikely that Jacob's or Pauline's children will be affected, unless they have married near or distant relatives. (2) Rachel should be cautioned against such a marriage. (3) Rebecca should certainly have no more children unless she is willing to expect idiot children in the proportion of one in every four, always remembering that in a small series the laws of chance are such that two or more affected children may follow one another, as in the previous generation.—I am, etc.,

Sheffield, Jan. 19th. ROBERT PLATT, M.D., M.R.C.P.

TONSIL AND ADENOID OPERATIONS.

SIR,—As a general surgeon I should like to emphasize, in a very few words, what Mr. J. Aldington Gibb has said in your issue of January 19th (p. 132), on the subject of haemorrhage following tonsillectomy. He says, "Haemorrhage after the guillotine operation usually means that a piece of tonsil has been left behind." No truer words than these have been spoken on the subject, and I will go even further and say that haemorrhage after any operation for tonsillectomy usually means incomplete eradication of the tonsil, excepting, of course, "bleeders" in all their phases.

Many years ago I was a victim of "dissection" at the hands of perhaps the greatest man of the time, and I well remember coming out of the anaesthetic, which had lasted for an hour and a half, biting on a gag, and no less than three pairs of Spencer Wells forceps affixed to bleeding points in my fauces. On a holiday a fortnight later on board ship I had a severe haemorrhage from the fauces, and have since had tags of tonsil removed on two occasions. Though this operation might by some be referred to the "dark ages," yet the haemorrhage was due to imperfect eradication of the tonsil, and it does not in one whit contradict what Mr. Gibb has said.

Having performed many hundreds of these operations as surgeon to a children's hospital I have witnessed only two cases of severe haemorrhage, both due to a piece of tonsil being left behind. For this reason I think that what appears a simple operation to-day is not without risks of a serious kind, and it should be left to an expert.—I am, etc.,

Bradford, Jan. 19th BASIL HUGHES.

SIR,—The importance of this subject and the sharp conflict of opinion expressed in your columns move me to take definitely and plainly a side in the controversy.

Despite the imposing array of contributors to the discussion who have proclaimed their adherence, for divers reasons, to the "let it rip" method of treating tonsil bleeding, I am bold enough to challenge their opinions and practice. Surgeons, as we all know, vary regarding their sensitiveness to haemorrhage, and the more sensitive encounter more haemorrhage: the less, less. Personally, I am afraid that in earlier years I belonged to the latter variety, until a succession of humiliating and most uncomfortable afternoons led to a sharpening-up of my reactions.

Haemorrhage, during and after operation for the removal of tonsils, sufficiently severe to blanch the patient, is not uncommon if the surgeon contents himself merely with gauze or other temporary pressure. But death therefrom is rare. When it does occur it is apt to escape the attention—the frank attention—of the surgeon's mind, by masquerading under the title of a death from "shock," or "delayed chloroform poisoning" (characterized, be it said, by the vomiting of large quantities of dark liquid). The young operator would do well, therefore, to make a point of ligaturing all bleeding points that do not stop after a reasonable amount of pressure by gauze or pressure forceps, just as he would similar points in an external neck wound. Why the tonsil wound should be exempted from the ordinary rules of operative surgery, and by what magic it is free from the risks of wounds elsewhere, I confess I do not understand, in spite of the firm and decided tone of the "let it rippers." The fear of ligatures setting up sepsis is a bogy and may be safely ignored.

Finally, let me say that my experience as an operator, the experience of more years than I care to number, leads me to agree with every word that Mr. Tilley has written.—I am, etc.,

London, W.1, Jan. 19th. DAN MCKENZIE.

SIR,—I should like to endorse the views expressed by Dr. Lindley Sewell in your issue of January 12th (p. 84). Practically bloodless tonsil enucleation can be achieved with the La Force guillotine. This scores over other two-bladed guillotines which I have tried in the past two years, in that a crushing force can be applied which is many times greater than that of any other type I know. Hence the efficient haemostasis. One of its defects is that the cutting blade must be carefully readjusted after each tonsil is removed, otherwise the sharp blade may be sent home first, which would negative the bloodless object of the operation. This unnecessary obtrusion of the cutting blade is a definite objection when one considers that its function is quite subsidiary. The tonsil could equally well be cut off the crushing blade with a pair of scissors.

I hope to publish shortly details of a new guillotine and technique which I have used for the past six months. I utilize the recoil of the crushing blade when the latter is released from its crushed stump to set back automatically the cutting blade. This simple, fool-proof device makes it impossible to close the instrument sharp blade foremost. The crushing and locking device is mechanically more simple and powerful, and practically instantaneous, being effected by one half turn of a lever. These features make it, I think, almost as easy to use as an ordinary guillotine.

With regard to haemostasis, my results are practically identical with those of Dr. Sewell. If Dr. Sewell were to incorporate the "non-skid head" in his instrument (*British Medical Journal*, October 20th, 1928) I believe he could still further lower the figure of 5 per cent. of adult tonsils in which he finds it necessary to resort to dissection.

My recollection of Mr. Irwin Moore's condemnation is that it refers particularly to the torsion-avulsion manœuvres, in which the tonsil is literally torn out of its bed. Such crude procedures have no parallel in other departments of surgery, and, in the circumstances, the adjective "unsurgical" would appear to be particularly mild.—I am, etc.,

London, W.1, Jan. 13th. O. POPPER.

SIR,—Mr. Stuart-Low informs us that he "can never understand" this, and that he has "thought out" that, and has "given much attention" to the other. He also informs us that he "said some time ago" something about chloroform. It would be more interesting for us to know how many operations he has done under chloroform with how many deaths, if any.—I am, etc.,

Kensington, January 20th. J. MCNAMARA, M.D.

ASTHMA.

SIR,—With Mr. Frank Coke's complaint in the *Journal* of January 19th (p. 133) I sympathize. The impression given by the joint letter which he criticizes is too lugubrious as to the prognosis of asthma. Extended experience only confirms what I wrote in 1913: "there is no distressing and disabling diseased condition more amenable to correct handling than asthma." Others have confirmed that statement and I hope will again confirm it, so I content myself here by adding (what I have also said before) that in 50 per cent. of asthmatics the ailment begins before the age of 16, and that of these at least 90 per cent. can be cured, and stay cured, if treatment be begun before that age and the patient is not permanently a mouth-breather. The percentage, of course, steadily diminishes with duration of the ailment, and especially in senile asthma, but the general statement above in inverted commas remains true.

The most important remedial agent is a way of life. Heredity and infections are important causal factors; but asthma is largely a disease of civilization and the indoor life, and it is largely by a rational ordered way of life it can be met. Nevertheless, the more research, and particularly biochemical research, we have the better; it is surprising that this has been so much neglected.—I am, etc.,

Glasgow, Jan. 20th. JAMES ADAM.

SIR,—Mr. Frank Coke has stated very clearly the mischievous effect of "the ancient parrot cry that there is no cure for asthma," which is a totally illogical perversion of the truth as expressed by Sir Humphry Rolleston, Lord Dawson, Dr. Hurst, and Dr. Fremantle that "there is not any one form of treatment which is effective in all forms of asthma." He refers to methods which have cured scores of cases, but strangely omits one from which the most gratifying results have been obtained—namely, the judicious treatment of the nose. No one who has acquainted himself with the experiments of Dixon on the etiology of asthma (*Trans. Path. Soc.*, London, vol. liv, p. 17, and *Journ. of Physiol.*, vol. xlv) can entertain any doubt as to the share which nasal disease can take in the production of the asthmatic "explosion," even if only as the "detonator" which fires the cartridge." In these experiments it was found that in the decerebrate animal contraction of the bronchial muscle could be brought about by irritation of the nasal mucous membrane, especially in the upper and posterior part of the septum.

There is ample clinical evidence that judicious nasal treatment (as Mr. Coke says of other procedures) has "led to such an amelioration of symptoms as many patients are satisfied to call a cure."—I am, etc.,

London, Jan. 21st. JAMES DUNDAS-GRANT.

SIR,—Mr. Coke appears to have misinterpreted the statement in the publicity campaign of the Asthma Research Council of which he complains. It did not state that there was no cure for asthma; it merely emphasized the fact that no "certain cure" had been discovered. As the editorial footnote to his letter in your issue of January 19th (p. 134) added, this is far less misleading than to announce that "a certain cure" for asthma had been found, and the position was accurately and concisely stated by "there is not any one form of treatment which is effective in all cases of asthma." Surely Mr. Coke will agree with this, even though he could have devised a better method of evoking the financial support of the public for a comprehensive scheme of research. The Asthma Research Council has, however, no cause to complain of the financial support it has obtained, so far, as a result of the Mansion House meeting on January 15th.—I am, etc.,

T. T. JEANS,
Surgeon Rear-Admiral,
Medical Secretary, Medical Advisory Committee.

London, S.W.1, Jan. 21st.

CARDIOSPASM OR ACHALASIA OF THE CARDIA.

SIR,—I wish to thank Dr. Hurst for his letter in your issue of January 12th (p. 83) replying to my questions in the previous issue, but the answers are not very convincing.

In the first reply he begs the question completely when he states that "cardiospasm or achalasia of the cardia is obviously a condition of the cardia and of nothing else." Merely to state the fact that two names, devised to express two opposed theories, both include the word "cardia," is no argument at all. It would be just as reasonable to say that because hysteria is so called, it must obviously be an affection of the uterus and of nothing else. My point is that neither name is entirely satisfactory, partly because a similar condition does occur in the oesophagus at a distance from the cardia and there appear to be no sufficient grounds for assuming a different pathology. Dr. Hurst says he has only met one such case, but I can add three others apart from those in the literature, and they are not great rarities.

I still find it difficult to believe that a feeble sphincter like the cardia could grip the mercury tube as firmly as the anal sphincter can grip the finger unless the cardia were greatly hypertrophied, but Dr. Hurst agrees that such hypertrophy does not occur. I have watched the *x*-ray screening of these cases on various occasions, and frequently, after some minutes, the opaque meal begins slowly to trickle through into the stomach, even without an eight inch column. In one case the barium meal at first passed into the stomach without any evidence of obstruction, and then the cardia closed and no more passed through for about five minutes. This would suggest an active closure rather than achalasia, but I never found any gripping of the mercury tube.

I am not well versed in mechanics, but I should have thought that, in his answer to question 5, the comparison with the safety valve of a boiler did not help his theory of achalasia. Surely the action of a safety valve more nearly resembles an active contraction—or spasm—than a failure of relaxation. When the pressure within the boiler rises sufficiently high steam escapes, but as soon as the pressure falls there is an active closure of the valve brought about by a spring or other means. When the cardia is forced open by the weight of more than eight inches of food in the oesophagus, how can an "inability to relax" make it close again?

Dr. Hurst does not deny the possibility of spasm of the cardia or of other parts of the oesophagus, and I do not suggest that achalasia of the cardia does not exist. Indeed, it would seem to be one of the necessary results of complete degeneration of Auerbach's plexus. It appears to me that the condition is an affection of the oesophagus, as a whole or in any part, and that both names at the head of this letter attempt to fix the lesion at one particular part—the cardia.—I am, etc.,

London, W.1, Jan. 14th. C. C. BEATTY.

LIPIODOL.

SIR,—I get my lipiodol from a French firm, and as they advertised a special lipiodol syringe I applied for one on approval. It had a screw piston action and cannulae of different sizes screwed on to it, but there were no trocars supplied, showing that on the Continent and elsewhere where this syringe was used the operator had to cut right into the trachea. I take it that what your reviewer meant in his criticism of the book by Drs. Chandler and Burton Wood (January 5th, p. 21) was that a little slit should be made in the anaesthetized skin, the cannula and trocar being then introduced and pushed home. I am using Dr. Chandler's cannula and trocar now, and agree with your reviewer about the slit, as it accelerates the operation and causes less manipulation. I have just injected lipiodol into a patient who has a left side thoracoplasty with a discharging sinus, through which a good amount of pus periodically comes, and it will be interesting to see if the sinus is discharging from a bronchus or not.

Lipiodol will be useful in a small percentage of cases, but the operation is not pleasant to the patient, and the one thing against the use of the scalpel is that it adds to the psychological and unavoidable thought that he is "feeling his throat cut," as one patient expressed it to me.—I am, etc.,

Winsley, Jan. 20th. J. D. MACFIE.

DENTAL CARIES AND VITAMIN D.

SIR,—For more than two decades I have had under my professional care as school dentist many thousands of children for the whole period of their school lives. One lesson I have learned is to distrust these cases of so-called "arrested caries," and, from the frequency with which, after a time, extraction of such teeth has to be resorted to, I very much doubt whether the "arrest" is ever complete and final. This view, I think, finds some support from the Mellanby-Pattison paper, for the writers tell us that even in those sections of teeth where caries appeared to be completely arrested the dentinal tubules contained micro-organisms—though these latter, most obligingly, were apparently inactive. Also in Case 1 (of K. C., aged 3½) a tooth was extracted though arrest was taking place, and on being examined microscopically showed organisms "still present in patches." Now why, in so young a child, was that tooth extracted? It is a fair question to ask, and it ought to be answered.

If all these cases were followed up, not only for weeks or months, but for years, it is more than probable that the "bacterial onslaught," so far from being completely arrested, would be found still possessed of great powers of mischief. Was it not so in the case of K. C., aged only 3½?

Most of the points have already been dealt with by your earlier correspondents, Dr. Harry Campbell, Dr. Sim Wallace, and Mr. Barwise, with whose views I am in

complete accord. There is, however, one other feature of the investigation to which I feel bound to call attention. The children concerned were very young, and all had eight or nine badly carious teeth. Apparently it was found possible to probe the carious cavities with sufficient force to record in some way the degree of resistance met with. Where, then, was the difficulty, with such well-controlled children, of deciding whether certain teeth were dead or alive? Why could not the usual tests be applied to determine the point? It was evidently regarded as important, but it was found "impossible in many cases" to be sure of one way or the other. May I suggest that in a purely dental investigation, sponsored on the one part by the Dental Board, such an admission is truly surprising.

For my part I should rejoice if a short cut to the prevention and cure of dental caries could be found; but I know too well how it is brought about to have any doubt as to the right lines on which to proceed, if it is to be avoided—and in this connexion it would be difficult to overstate my indebtedness to the teaching and writings of Dr. Sim Wallace.—I am, etc.,

London, S.W., Jan. 13th. FREDK. BREESE.

THE DOCTOR AND CHEMICAL WARFARE.

SIR,—In your annotation on an article by Dr. Lockhart in the January *National Review* it is suggested that attempts to prepare the medical profession to meet attacks upon the civil population in the guise of chemicals from the air should await the discovery of an antidote to injury caused by poison gas. Dr. Lockhart's admirable article suggests both the necessity for an organization to meet an attack and the form the organization should take. Your suggestion is for treatment; his is for prevention.

The enormous number of persons likely to suffer in an attack upon one of our huge and densely populated towns may be gauged by the effect of the first use of poison gas upon unprepared troops at Ypres in 1915, when 5,000 were killed in five minutes and a very large number of casualties occurred. Surely to organize beforehand is a better way to prevent the terrible panic and loss of life certain to follow a gas attack from the air than to await the arrival of an antidote, however valuable; since several gases are likely to be employed in the attack, and there can be no certainty as to the nature of any of them, the chance of getting any such antidote to the expected casualty in time to be of any value is unlikely, and its value problematical.

In my manual on the protection of the civil population in chemical warfare, published by the St. John Ambulance Association (see *Journal*, December 29th, 1928, p. 1202), there is a description in a simple form of the principles and some of the details of an organization very similar to that of Squadron Leader Lawrence which was mentioned in your annotation. I venture to suggest that the subject as a whole is a very fitting one for the British Medical Association to take up; it might issue some practical scheme for the use of medical practitioners, in conjunction, of course, with the War Office Department for Chemical Warfare. There is much preparation to be done, and the available time may not be more than is necessary.—I am, etc.,

Wokingham, Jan. 14th. F. R. HUMPHREYS.

RADIUM AND CANCER.

SIR,—The letter which appeared in your issue of January 5th (p. 42), over the signature of the professor of physics at Trinity College, Dublin, on the subject of priority of claim to the radium needle technique, is timely. When I was working in the cancer research laboratories of the Middlesex Hospital in 1913 and 1914 Dr. W. C. Stevenson, during his visits to us, discussed the technique of treating malignant disease by small doses of radium put up in needles. His paper on this subject was read with great interest.

It is a pity that some of those who have been converted to believe in the value of radium therapy since the termination of the war should only quote our Continental colleagues as the originators of this particular technique.—I am, etc.,

A. CLIFFORD MORSON.

London, W.1, Jan. 21st

MEDICAL FOUNDATIONS.

SIR,—In your issue of January 5th (p. 40) Dr. Henry Robinson directed attention to two most excellent medical charities—namely, the Royal Medical Benevolent Fund and Epsom College. May I bring to the notice of your readers a third, the Society for Relief of Widows and Orphans of Medical Men, which is older than either of the two mentioned above, having been founded in 1788 and incorporated by Royal Charter in 1864? The objects of this society are to help the necessitous widows and orphans of its deceased members, and the income of the society enables it to make substantial grants yearly to those in need. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. The privileges of membership are, however, retained should a member remove outside the area. The annual subscription is very small—£2 2s., £3 3s., £4 4s., according to the age of the candidate. Should any medical man who resides within the area be desirous of joining the society, or any benefactor desire to give a donation or bequeath a legacy, I shall be pleased to send him full particulars.—I am, etc.,

EDWARD J. BLACKETT, Secretary.

Society for Relief of Widows and Orphans of Medical Men, 11, Chandos Street, Cavendish Square, W.1, Jan. 10th.

Obituary.

DR. FRANCIS WILLIAM HARTLEY, whose death occurred from pneumonia, while on holiday at Llandudno, on January 1st, at the age of 63, retired from practice at Heywood, Lancashire, three years ago, after spending the greater part of his professional life in that, his native town. He received his medical education at Owens College, Manchester, and obtained the diplomas M.R.C.S., L.R.C.P. in 1893. After serving as an assistant in various towns for several years he began practice on his own account in Heywood. During the war he held a commission in the R.A.M.C. and served for a time in the South of England. He was keenly interested in professional affairs, and in the Rochdale and District Medical Society was president in 1913–14 and vice-president in 1920–21. He was also a member of the British Medical Association. We are indebted to a colleague for the following appreciation: Although a very loyal member of the Association and a regular attendant at meetings, Dr. Hartley could not be persuaded, owing to his retiring disposition, to accept any office, but; nevertheless, he always exercised a very real influence among his colleagues, having a high ideal of duty and professional behaviour, which he maintained with unfailing courtesy. The loss of his son at the age of 16, last spring, was a severe blow, borne with typical fortitude. Dr. Hartley is survived by his widow and one daughter. His funeral on January 3rd at Heywood was attended by several of his colleagues and by a large gathering of his former patients, who came to mourn the passing of a "very perfect gentleman."

We regret to record the death from septic pneumonia of Mr. JOHN LISTER WRIGHT, which took place at his home at Southsea on January 4th. In the Portsmouth district, where he had practised for many years, he was very well known and highly respected, and had been, at an earlier period, equally prominent in medical circles in Derby. He was born in 1859 at Launceston in Cornwall—where his father was in practice—and subsequently removed with his family to Wynberg, near Capetown, in South Africa, where he received his early education at the Diocesan College. He afterwards came to England, and pursued his medical studies at St. Bartholomew's Hospital, obtaining the diplomas M.R.C.S.Eng. and L.R.C.P.Ed. in 1884. A few months afterwards he returned to South Africa, and was appointed assistant resident surgeon to the New Somerset Hospital at Capetown. Two years later he joined his uncle, Dr. F. W. Wright, in Derby, and later succeeded him in practice in that town. Mr. Lister Wright had a preference for surgical work, and he was before long

appointed surgeon to the Derbyshire Hospital for Sick Children, an office which he held for about five years. Later he was elected to the surgical staff of the Derbyshire Royal Infirmary, but his work in this capacity was cut short by the failure of his health, which necessitated his removal to the South of England. Mr. Wright obtained a commission in the R.A.M.C. on the formation of the Territorial Force, and during the war served as a captain with the 5th Southern General Hospital at Portsmouth. He was medical officer to the Portsmouth and Isle of Wight Home and School for the Blind for twenty-seven years. His connexion with the British Medical Association extended over a considerable period, and from 1904 to 1907 he was a member of the Executive Committee of the Portsmouth Division. Although his interest in professional affairs was keen, he was of a somewhat retiring nature, and his kindly disposition and idealistic outlook led him to avoid controversy and conflict. At the funeral service in Portsmouth Cathedral Church the Bishop of Portsmouth paid a notable tribute to the personal and professional qualities of Mr. Lister Wright. Among those present were many members of the medical profession, including Dr. F. C. B. Gittings, honorary secretary of the Portsmouth Division of the British Medical Association. Mr. Wright leaves a widow and one daughter.

Dr. ROBERT GEORGE DE LA POER BERESFORD, whose death occurred on January 14th, at the age of 86, had spent about sixty years in practice at Oswestry, and had been mayor of that town for two years. He received his medical education at the Ledwich School of Medicine in Dublin and at the University of Glasgow, and in 1865 obtained the diplomas L.R.C.P. and L.R.C.S.Ed.; four years later he obtained the diploma L.R.C.P.Lond., and in 1871 he graduated M.D.Glas. Many years afterwards he renewed his studies, and so recently as 1916 obtained the D.P.H. of Liverpool University. After qualifying he held resident posts in Dublin, at Cork Street Fever Hospital and at Mercer's Hospital, subsequently commencing practice at Oswestry. Dr. Beresford was closely associated with the work of a number of institutions in that area; he was at one time physician to the Oswestry Joint Infectious Hospital, surgeon to the Cambrian Railway Company, and at the time of his death was consulting surgeon to the Oswestry Dispensary and the Oswestry and Ellesmere Cottage Hospital. He had completed fifty years' service in this capacity when, in 1927, he resigned his part-time appointment as medical officer of health for the Oswestry rural and urban districts. His association with the auxiliary forces as a medical officer covered many years also; he received the Volunteer Decoration, and retired after reaching the rank of surgeon-colonel. During the war he served as senior surgeon at the Oswestry Auxiliary Military Hospital. He took a keen interest in medical affairs, and was a Fellow of the Society of Medical Officers of Health, of the Royal Institute of Public Health, and of the Chemical Society. He was also an honorary serving brother of the Order of St. John. His many services to Oswestry and district were recognized in 1927, when he received the freedom of the borough. He was also a justice of the peace for the county of Salop.

Dr. DAVID JAMES GRAHAM, who died at a sanatorium in Aberdeenshire on January 14th, after a long illness, was a well-known Edinburgh practitioner. Not long after his return from military service in France Dr. Graham contracted a disorder in the throat which compelled him to lay aside active work, and despite his pursuit of health in various places the disease ultimately spread to the lungs and caused his death. He received his medical education at Edinburgh University, and graduated M.B., C.M. in 1895, proceeding M.D. in 1899. At the time of graduation he obtained the James Scott scholarship in midwifery, and he was afterwards successively assistant medical officer at the City Hospital for Infectious Diseases, Edinburgh, and resident medical officer in Chalmers Hospital, Edinburgh. He obtained the Membership of the Royal College of Physicians of Edinburgh in 1898, proceeding to its Fellowship in 1901. After commencing general practice, he was assistant to Dr. Haig Ferguson for several years. Dr. Graham gradually established an extensive practice, and held several public appointments, including those of medical officer to Donaldson's Hospital and to George Heriot's School, and surgeon apothecary to His Majesty's household at Holyrood Palace. For a short time he acted as physician to the Royal Public Dispensary, Edinburgh. Shortly after the formation of the Territorial Force he joined the 3rd Lowland Field Ambulance, and was later transferred to the 2nd General Scottish Hospital as registrar, in which capacity he served for some three years during the war before proceeding to France. In the neighbourhood of St. Omer and at Etaples he acted as commanding officer of the 58th and 11th Scottish General Hospitals, and for his services was awarded the O.B.E. He received the Territorial Decoration, and retired from the force with the rank of brevet colonel. He took an active interest in the V.A.D. service and Red Cross work before the war, and on his return from military service this interest was continued in the reorganization of the Red Cross work on a peace footing. His interest in professional affairs was not limited to any one aspect; he was a Fellow of the Edinburgh Obstetrical Society and of the Edinburgh Medico-Chirurgical Society, and a member of the Royal Medico-Psychological Association. He was also for many years a member of the British Medical Association. The sympathy and affection of many friends and patients, gained by his early work in practice, were increased by his vain search for health in recent years, and his death will be deplored by many friends in Edinburgh. Dr. Graham is survived by a widow, a son, and a daughter.

Dr. ARTHUR HENRY HEADLEY HUCKLE, who died suddenly on January 13th, after a long period of ill health, was well known and deeply respected in East Sussex, where he had been in practice in Hastings for many years. Born in Australia in 1870, he came to England at an early age, and was educated at Dulwich College, pursuing his medical studies subsequently at Guy's Hospital. In 1895 he obtained the diplomas M.R.C.S.Eng., L.R.C.P.Lond., and L.S.A., having, a year before, qualified as a Licentiate in Dental Surgery in the Royal College of Surgeons. Later he was called to the Bar as a member of the Middle Temple, and in 1910 he obtained the D.P.H. of the English Royal Colleges. In Hastings Dr. Huckle built up an extensive practice, and held a number of public and other appointments, the nature of which will serve to indicate the wide range of his interests. He was consulting physician to the Hastings Union Infirmary, medical superintendent of the Hastings Borough Sanatorium, honorary pathologist and honorary dermatologist to the East Sussex Hospital, and medical officer to the Hastings and East Sussex Venereal Disease Clinic. He was also a member of the British Medical Association and of the East Sussex Medico-Chirurgical Society. Among outside affairs Freemasonry was perhaps his chief interest. He was a justice of the peace. We are indebted to Dr. William Gover for the following tribute: The sudden death of Arthur Headley Huckle has come as a personal grief to many of his colleagues, in whose affections and esteem he held a high place. He had been in poor health for some months, but the end came unexpectedly. Huckle was a man of very wide knowledge. He had qualified in dentistry and had been called to the Bar, while years of general practice, illuminated by constant study, had given him a vast experience, which he placed at the disposal of his friends in a spirit of humility and self-effacement that was entirely characteristic. Of late years he had somewhat contracted the sphere of his activities, and devoted himself mainly to pathology, fevers, and venereal disease. In the laboratory he was a pioneer, for ever trying out some new line of treatment or fresh method of diagnosis, with all the enthusiasm of youth. His work in the sanatorium was on the same plane. His treatment of fevers always gave confidence to brother practitioners and to patients alike, and they knew that any fresh discovery in medicine would be immediately available. If Huckle could not save a case no one else could have done so. It was perhaps in the

venereal diseases clinic, where the qualities of a gentleman are most required, that he seemed particularly to shine, and where his sympathetic understanding, kindly tact, and vast knowledge of medicine had their widest scope. It would hardly appear possible to fill the gap he has left.

VITAL STATISTICS FOR ENGLAND AND WALES, 1928.

We are indebted to the Registrar-General for the following statement regarding the birth rates and death rates and the rates of infantile mortality in England and Wales and in certain parts of the country during 1928. The statement is issued for the information of medical officers of health. The birth rate and infantile mortality rate for London have been provisionally corrected for transfers.

ENGLAND AND WALES.

Birth Rate, Death Rate, and Infantile Mortality during the Year 1928 (Provisional Figures).

	Live Births per 1,000 Population.	Deaths per 1,000 Population (Crude Rate).	Deaths under One Year per 1,000 Live Births.
England and Wales (on 1928 estimated population)	16.7	11.7	65
107 county boroughs and great tow... [illegible] London (on 192 156 ...ilations from 20,000 ... in 1921—on 1927 estimated population)	16.9 16.7	11.6 10.6	70 59
London (on 1927 estimated population)	15.9	11.6	67

The death rate for England and Wales relates to the whole population, but that for London and the two groups of towns to the civil population only.

England and Wales.

The birth rate is 0.1 per 1,000 above that of 1927. The death rate is 0.6 per 1,000 below that of 1927, and only 0.1 per 1,000 above the lowest recorded (1923 and 1926). The infant mortality rate is the lowest on record, 4 per 1,000 births below that of 1923.

Universities and Colleges.

UNIVERSITY OF OXFORD.

A RHODES Travelling Fellowship has been awarded to Malcolm H. MacKeith, M.D., Fellow of Magdalen College.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on January 18th the following medical degrees were conferred:

M.B., B.Chir.—S. W. Savage, F. Smith.
B.Chir.—L. Foulds, E. Clayton-Jones, A. J. Dix-Perkins, H. F. Bateman, L. T. Hilliard, J. C. F. Lloyd-Williamson.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

At the second winter commencements, held on January 19th, the degree of M.D. was conferred on H. E. Murray of the Indian Medical Service.

The Services.

NAVAL MEDICAL COMPASSIONATE FUND.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on January 22nd, when Surgeon Vice-Admiral Arthur Gaskell, C.B., O.B.E., Medical Director-General of the Navy, was in the chair, the sum of £100 was distributed among the several applicants.

DEATHS IN THE SERVICES.

Surgeon Lieutenant Henry Johnson Scott, R.N., was recently drowned at Shanghai. He was educated at Glasgow University, where he graduated as M.B. and Ch.B. in 1925, took a short service commission in the navy on July 9th, 1926, and was posted to H.M.S. *Cricket*, on which he was serving at the time of his death, on September 22nd, 1928.

Major Alexander Oswald Cowan Watson, R.A.M.C.(ret.), died suddenly in Edinburgh on January 4th, aged 70. He was born in Bombay on November 7th, 1858, the second son of the late Rev. Alexander Boog Watson, LL.D., of Cardross, and was educated at Edinburgh University, where he graduated as M.B. and C.M. in 1883, after taking the L.R.C.S. and P.Ed. in 1882, and subsequently took the F.R.C.S.Ed. in 1889 and the B.Sc. in public health of Edinburgh in 1897. He also studied in Aberdeen, London, and Vienna. Entering the army as surgeon on February 5th, 1887, he became major after twelve years' service, and retired on September 5th, 1908.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Both Houses of Parliament assembled on January 22nd to resume a session which may end with a dissolution about Whitsuntide. In the Commons three more days were assigned to the Committee stage of the Local Government Bill. Discussions were arranged in the House of Lords on de-rating and on the Channel tunnel.

A meeting of the Parliamentary Medical Committee was summoned for January 23rd. The business proposed was discussion of the public health clauses of the Local Government Bill. An application suggesting a conference on the bill was before the Committee from the Society of Medical Superintendents, as was also a proposal from the National Council of Social Service for an interview with the Committee about prescribing under the National Health Insurance Act.

Local Government Bill.

Consideration of the Local Government Bill in committee was resumed in the House of Commons on January 22nd, this being the fifth allotted day under the time-table motion. On Clause 55, which gives relief from rates in respect of industrial and freight transport hereditaments, Mr. BRIGGS moved an amendment to exclude from the benefits of de-rating breweries, distilleries, and tobacco factories. Mr. CHAMBERLAIN resisted the amendment. Miss WILKINSON, in supporting the amendment, said that the common sense of the country, and especially of the women, would be against handing over this public money to the liquor and tobacco industries, when the Government was cutting down the grants for maternity and child welfare. The grants for milk and nursing mothers were also being reduced. Yet this was at the moment when the Queen had written to the newspapers to say that she was disturbed by the appalling increase in deaths in cases of motherhood. The amendment was rejected by 84 votes. Clauses 56 to 67, which were subsequently passed, dealt largely with adaptations of enactments.

Slum Clearance Schemes.—Sir KINGSLEY WOOD, on January 22nd, told Commander Kenworthy that between April 1st, 1925, and December 31st, 1928, the latest date for which particulars had been furnished, 8,540 buildings had been acquired for demolition, 6,092 buildings had been demolished, and 6,949 new dwellings had been erected in connexion with slum clearance schemes. Approximately 31,000 persons had been rehoused in these new dwellings. Commander KENWORTHY asked if there was any prospect of these operations being expedited. Sir KINGSLEY WOOD replied that local authorities were displaying more vigour in slum clearance schemes. Sir J. GILMOUR, replying to Mr. Stephen, said that the total number of houses completed in Glasgow under slum clearance schemes was 996 in 1926 and 838 in 1927. The number of slum houses in the city remaining to be dealt with was estimated to be 13,000.

Medical News.

At the meeting of the Royal Sanitary Institute to be held at 90, Buckingham Palace Road, S.W., on Friday, February 1st, Dr. F. R. Humphreys will open a discussion on the civil population and chemical warfare. The chair will be taken by the Earl of Halsbury at 5 p.m.

A POST-GRADUATE course in orthopaedic surgery will be held at the Royal National Orthopaedic Hospital, 234, Great Portland Street, W.1, from March 11th to 23rd, with lectures and demonstrations daily. Further particulars may be obtained from the secretary of the Hospital or from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that Mr. Malcolm Hepburn will give a lecture on "Some apparent difficulties of general practitioners in ophthalmic work" at the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Monday, January 28th, at 5 o'clock. On the following day, at 4.30 p.m., Dr. Batty Shaw will give a clinical demonstra-

tion at the Brompton Hospital for Consumption, and at 4 p.m. Mr. Rodney Maingot will lecture on "The injection treatment of varicose veins," with a demonstration of the methods and results in over fifty cases, at the Royal Waterloo Hospital. Dr. R. A. O'Brien will demonstrate the prophylactic and therapeutic value of vaccines and serums in general practice at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C., on Wednesday, January 30th, at 4 p.m. There is no fee for attendance at these lectures and demonstrations. At the Prince of Wales's General Hospital a two weeks' intensive course in medicine, surgery, and the specialties will begin on January 28th, while from January 29th to February 2nd a series of lecture-demonstrations in psychological medicine will be given at the Bethlem Royal Hospital. Special [illegible] February will deal with gynaecology, [illegible] of the chest and of children, and neurology. Detailed syllabuses and information regarding the general course may be had from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE new recreation and lecture rooms at the Queen Mary's Home for St. Bartholomew's Nurses were opened by Sir Kynaston Studd, Lord Mayor of London, on January 17th. The new rooms lie immediately behind the main buildings of the home, which provides accommodation for 312 nurses and superintendents.

WESTMINSTER HOSPITAL has received a cheque for £2,000 from an anonymous donor towards the erection by the hospital of scientific laboratories in connexion with the new radium annexe to be opened shortly.

THE Queen has given her consent to the new wing of the Elizabeth Garrett Anderson Hospital being named "The Queen's Wing." At the official opening of the hospital in the spring she will receive the purses and casket of jewels that are at present being collected. It is intended to utilize the proceeds of the sale of the jewels for the endowment of a bed. The new building has already been completed and equipped, and was recently dedicated.

AN appeal has been issued for financial support for the Industrial Health Education Society, signed by Sir Humphry Rolleston, the honorary president. The society, which was formed about three years ago, exists to provide information and advice to industrial workers on occupational diseases, personal hygiene, general health, and accident prevention largely by means of lectures by medical men. Its work has gained a wide measure of support among members of the medical profession, employers of labour, and representatives of employees' organizations. Several pamphlets have been prepared and circulated. An account of the activities of the society was given in the *Journal* of April 7th, 1928 (p. 605). Hitherto no request has been made for outside assistance, but the expansion of its work has made it necessary to raise the sum of £5,000 to meet the demands made upon it. Communications regarding the appeal or the work of the society should be addressed to the general secretary, Mr. James Mackenzie, 84, Kingsway, W.C.2.

THE late Mrs. Sowerby of Cumwhinton, near Carlisle, has left the residue of her estate, which will probably amount to about £6,000, to the Cumberland Infirmary.

THE second congress of the German Society for the *Investigation of the Circulation* will be held on March 4th and 5th at Bad Nauheim, when papers will be read on the signs of age and wear in the vessels, by Dr. Gruber of Göttingen, and on oedema and its treatment, by Dr. Nonnenbruch of Prague. Further information can be obtained from Dr. Arthur Weber, Nauheim.

THE fourth Congress of Industrial Medicine will be held at Lyons on April 3rd, 1929, when the following subjects will be discussed: (1) silicosis, introduced by Dr. Mavrogordato (South Africa), Professor Boehme (Germany), Professor Irvine (South Africa), Professor E. L. Collis (Great Britain), Professor Thiele and Professor Sternberg (Germany); (2) cataract as an industrial disease, introduced by Professor Elschnig (Czechoslovakia) and Professor Rollet (France); (3) endocrine organs and intoxications, introduced by the Italian Professors C. Biondi, L. Ferranini, and N. Prude. Further information can be obtained from the secretary, Dr. Mazel, 54, Avenue de Noailles, Lyons.

THE thirty-third congress of French-speaking alienists and neurologists will be held at Barcelona from April 3rd to 9th, under the presidency of Dr. Lalaune, medical superintendent of the Mareville Asylum (Meurthe-et-Moselle), and Dr. Jimeno-Rieto, director of the National Asylum at Saragossa. The following subjects among others will be discussed: hereditary syphilis in the etiology of mental disease, sensory symptoms in disseminated sclerosis, and psychiatric examination of criminals.

AN International Congress of Medical Women will be held in Paris from April 11th to 15th.

THE second international congress on malaria will be held at Algiers from May 19th to 21st, 1930, simultaneously with the celebration of the fiftieth anniversary of Laveran's discovery of the *Plasmodium malariae*. Further information can be obtained from the General Secretary, Institut Pasteur, Algiers.

THE following appointments have recently been made in the French faculties of medicine: Dr. Labat as successor of Professor Barthe in the chair of toxicology and hygiene, and Dr. Henri Bonnin as successor of Professor Le Dantec in the chair of colonial medicine and tropical diseases at Bordeaux, Dr. Carrière, professor of children's diseases, as successor of Professor Lemoine in the chair of clinical medicine; and Dr. Minet, professor of therapeutics, as successor of Dr. Carrière in the chair of children's diseases at Lille.

THE Academy of Sciences, Medical Faculty, and Medical Society of Vienna have jointly set up a committee to arrange for the celebration, on April 26th, of the centenary of the birth of the celebrated Vienna surgeon, Theodor Billroth, who died in 1894.

THE Health and Cleanliness Council has published two excellent little pamphlets—*Health and Beauty*, by Miss Edith A. Cocher and Dr. Elizabeth Foley, and *Keep Fit*, by Colonel R. J. Blackham, M.D., and Mr. George H. Green—intended for distribution to girls and boys respectively. Supplies are offered free of charge to teachers whose charges are about to leave school and to the leaders of juvenile clubs and organizations. Both booklets are clearly written and brightly illustrated, and contain a wealth of common sense and practical advice. They are commendably free from the error of "preaching," which young people are quick to detect and resent. Inquiries about supplies should be addressed to the secretary of the Council, 5, Tavistock Square, London, W.C.1.

EDWARD ARNOLD AND Co. announce for early publication a second and enlarged edition of Professor Robert Muir's *Textbook of Pathology*.

IN a supplement to the issue of *Nature*, dated January 19th, is published an abridged and revised version of Professor A. E. Boycott's presidential address on filterable viruses, delivered on October 16th, 1928, before the Section of Pathology of the Royal Society of Medicine.

WE have received the first issue of a new monthly journal entitled *Le praticien du Nord de l'Afrique*, published under the editorship of Dr. L. Prou at Algiers, which already possesses two other medical journals—*L'Algérie médicale* and *La Revue générale de médecine et chirurgie de l'Afrique du Nord*. The issue contains original articles on pneumotomy in gangrene of the lung, treatment of gastric atony, synechiae of the nasal fossae and their treatment by diathermy, pleural eclampsia in artificial pneumothorax, clinical notes, abstracts from current literature, and reviews of books.

THE *Year Book* for 1929 of the United Kingdom Alliance contains, in addition to a variety of material relating to the temperance question and relevant statistical matter, an interesting article on "The place of the alcohol question in social hygiene," by Sir Arthur Newsholme, who discusses the effects of the use of alcohol particularly in relation to health. The *Year Book* may be obtained from the office of the Alliance, 1, Victoria Street, S.W.1, price 2s.

THE Alvarenga prize of 300 dollars offered by the College of Physicians of Philadelphia for the best original work on any subject in medicine will be awarded on July 14th. Competitors should send in their essays to the secretary, Dr. John Girving, 19, South 22nd Street, Philadelphia, by May 1st.

A GIFT fund amounting to over £280,000, raised by the Swedish people in celebration of the seventieth birthday of King Gustaf V, is to be devoted to subsidizing a campaign against cancer. Six grams of pure radium, costing £63,000, have been purchased for distribution to various centres under the direction of Professor Goesta Forsell, and with the remainder of the fund it is intended to pay for the technical equipment of institutions engaged in cancer research.

MAJOR JOHN HERBERT BANKES, late R.A.M.C., has been appointed a deputy lieutenant for the County of London.

DR. CUNÉO has been elected president of the Société de Chirurgie, and Professor F. Besançon president of the Société Médical des Hôpitaux de Paris, for 1929.

THE tenth salon des médecins, organized by Dr. Paul Fabier for the exhibition of pictures, sculpture, engravings, and decorative art by medical and dental practitioners, veterinary surgeons, pharmacists, students, and their families, will be held at the Cercle de la Librairie, 117, Boulevard St. Germain, Paris, from April 21st to 30th.

A BELGIAN society of gastro-enterology has recently been founded at Brussels, under the presidency of Dr. Georges van Damme.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR of the *British Medical Journal*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

HOUSE AND SURGERY.

D. X., "who is about to have a house built with surgery attached, would be glad of practical information on this matter from any doctor with recent similar experience.

TREATMENT OF DEAFNESS.

"W. D. H." invites suggestions for the treatment of a very deaf man, aged 50. The blood pressure ranges between 120/240 and 140/300. The Wassermann reaction is positive, but there is no history of infection, which probably dates back at least six years. No improvement followed the administration for one month of potassium iodide gr. xlv, with fractional doses of calomel and lig. hydrarg. perchlor. daily, followed by six ten-daily injections of 914 intravenously and bismuth and thiosulphate intramuscularly. The deafness is increasing. The patient is not very tolerant of arsenic, the doses of which ranged from 0.15 to 0.45 gram. He is now taking 60 grains of potassium iodide daily. The urine shows a slight but definite trace of albumin, and the blood pressure is 130/260.

PAIN IN VARICOSE VEINS.

DR. ADA MCLAREN (London, W.1) writes: I think Dr. Duncan Greig would find the result satisfactory if he advises ultra-violet therapy in the case he writes about of pain in varicose veins. I have not had a failure during the four years I have used a tungsten lamp for that condition.

INCOME TAX.

Car Transaction.

"T. B. E." a year or two ago purchased a second-hand R 12-h.p. car for £200. In March of last year he sold it for £40 and bought a 14-h.p. M car for £250. He is now on the point of selling the M car for £76 and buying a 16-h.p. A car for £315; both transactions fall in the same financial year. What should he be allowed?

*** He cannot claim for the cost of improving his car equipment, but nominal horse-power is only one point for consideration out of several, and an increase in horse-power does not *necessarily* connote an increase in capital outlay. The allowances due are as follows:—*First transaction*: £200−£40=£160. There was some capital outlay here, as the first car was second-hand. *Second transaction*: £250−£76=£174. It is clear that there was capital improvement here. Taking the series of transactions as a whole "T. B. E." has expended £200+£250+£315=£765, and has received £40+£76=£116—that is, his net expenditure has been £765−£116=£649. The two allowances to be made are £160+£174=£334, which sum deducted from £649 leaves £315, the price of the car on which no allowance has yet become due.

LETTERS, NOTES, ETC.

RISK OF INFECTION FROM WASHING APPLIANCES.

DR. LACHLAN GRANT (Ballachulish) informs us that he has addressed to the chief medical officer of the Health Department of Scotland an "open letter" on some causes of the spread of infectious diseases and their prevention, in which he seeks to indicate the dangers to health associated with the use of the ordinary types of earthenware wash-hand basin (as commonly placed in bedrooms) and of lavatory wash-basin. Dr. Grant points out that in both types deposits of dirt of many kinds are frequently to be detected; even the lavatory type of basin, fitted with hot and cold water taps, is by no means satisfactory. A deposit is often left at the level of the water surface, which mixes with the clean water placed in the basin by the next user. Even the practice of allowing the water to run while washing does not, he considers, give much greater security from micro-organismal infection, and ordinary cleansing measures are not sufficient to ensure sterilization. Dr. Grant has carried out exhaustive examinations of lavatory basins in common use; on microscopical examination, following the centrifuging of the basin fluids, much filthy matter was detected, and bacteria of the cocci, bacilli, and spirilli classes were observed. In bacteriological tests, with culture media inoculated direct from the basins themselves, apart from the contaminating micro-organisms, like the *Bacillus subtilis* and numerous moulds, the two predominating growths were the ordinary pus-forming [illegible] *pyogenes* and *albus*—and the *Bacillus* [illegible] cocci, resembling the *Micrococcus ca* [illegible] a bacillus of the diphtheroid type. Dr. Grant suggests that the present methods of washing make for infection by the nasopharynx—the channel by which most infectious diseases are spread. His remedy is the fitting of all wash-basins with a raised tap (having a rose, spray wave, or jet outlet) removed some distance from the side of the basin, so as to avoid the need for contact with this source of contamination: by means of this appliance the washing of the hands and face would be done by the continuous use of pure, uncontaminated water. In his letter he describes at length the ideal type of fitting and explains its advantages; he gives a list of infectious likely to be disseminated by the present common type of basin, and indicates the dangers arising from their use by "carriers," finally emphasizing the importance of supplies of uncontaminated running water in maternity work. Dr. Grant urges the need for a publicity campaign to advocate the use of fittings of the new type, and suggests that a conference be summoned by the Minister of Health to consider the questions raised, and to arrange for further research in connexion with present-day sanitary appliances.

TREATMENT OF EMPYEMA.

DR. STUART TIDEY (London, W.) writes: The treatment of empyema has always been a source of anxiety to the surgeon, owing to the persistence of the suppurating cavity after the pus has been first evacuated. This is due in part to the rigidity of the thoracic wall not allowing the outer wall of the abscess cavity to fall in, and in part to the absence at the seat of lesion of the physiological pull which would normally keep the lung in contact with the chest wall. To overcome the obstruction to falling in of the chest wall it is the practice to resect portions of one or more ribs, a measure which is frequently successful. Pending rib resection, however, and in the event of resection being contraindicated by the condition of the patient, there is a simple measure which I have often found to be attended with gratifying results, namely: the constriction of the lower part of the chest wall by a bandage or binder passing directly over the lesion. The bandage may be kept from contact with the operation wound by means of a suitably adapted "surgical bridge," such as I described in the *Medical Press and Circular*, September 21st, 1927. The constriction compresses the lower thorax and its contents, thereby relaxing tension on the abscess cavity and allowing it to close. It must not be employed, however, till a free opening has been made for the escape of pus.

TREATMENT OF ASTHMA.

DR. W. J. MIDELTON (Bournemouth), referring to Dr. S. Gilbert Scott's article on the treatment of asthma by radiation (January 5th, p. 9), wishes to call attention to the value of such measures as the cautery, blisters, and irritants which promote the formation of pustules. He ascribes the benefit that follows in some cases to stimulation of the vagus or to local breaches in the skin, providing an outlet for toxins or leucocytes carrying micro-organisms.

MIXED HISTORY.

THE confusion in the lay press between the General Medical Council and the British Medical Association is interminable, so that it is perhaps no wonder that men of light and leading in other professions stumble at the same little stile. Not long ago a distinguished Cambridge professor referred in a public address to the "British Medical Council," but a new version (writes a correspondent) was forthcoming the other evening from a member of the council of the Royal Institute of British Architects, who was expounding to a general meeting a scheme of reform for that body. Drawing a parallel from the medical profession, he said that when doctors became registered "the two Royal Colleges were entirely swamped as an executive for voicing the views of the profession by the General Medical Council of the British Medical Association."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 27.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

82. Seasonal Variation of Infectious Diseases.

P. WORINGER (*Journ. Méd. de Lyon*, December 5th, 1928, p. 707) believes that the study and treatment of the exanthemata have been retarded by the fact that attention has been concentrated hitherto upon bacteriology to the exclusion of the consideration of other factors, such as seasonal variations, which have an important effect on human beings. Statistics of infectious diseases in temperate climates show that almost all conform to a type, either hiberno-vernal with a maximum prevalence in March, or aestivo-autumnal having a maximum incidence in September. To the first group belong pneumococcal, meningococcal, and streptococcal infections, tuberculosis, and epidemic encephalitis; in the second group are enteric fever, dysentery, cholera, and poliomyelitis. The only exception is diphtheria, which has a definitely hibernal incidence. Woringer believes that these seasonal variations are not due to changes in bacterial type, but to alterations in the patient's systemic resistance under changing meteorological conditions. In hiberno-vernal infections deficiency of sunlight has prepared the soil for infection, while sunlight reinforces cellular resistance. Woringer terms hiberno-vernal infections which are inhibited by sunlight "heliophobic," and aestivo-autumnal diseases which are not thus inhibited "heliophilic." The action of sunlight on heliophobic infections appears to be due to immunization through the skin, termed "dermophylaxis." The author finds it more difficult to determine the meteorological factor which prepares the soil in heliophilic diseases, and suggests that immunization in them does not occur in the skin, but in the intestine (enterophylaxis). He concludes that on these lines it is possible to define the exact position that helio-and actino-therapy should occupy in the fight against infection. Systematic employment of light as a prophylactic and therapeutic agent appears to reduce definitely the morbidity and mortality from heliophobic infections. He provides a number of curves showing the seasonal variations of different infections, and advocates the establishment of heliotherapeutic centres under medical supervision.

83. Paroxysmal Ventricular Tachycardia.

H. MOORE (*Irish Journ. Med. Sci.*, December, 1928, p. 754) describes a case of ventricular paroxysmal tachycardia, and contrasts the rarity of this condition with the relative frequency of auricular and nodal tachycardia. The patient, a boy aged 12, who had had no rheumatic manifestations, experienced an attack of violent palpitation following a severe fright. Five months later a similar attack occurred, and he was found to have moderate congestive failure with cyanosis; the pulse rate was 166 and regular. Vagal pressure gave no result. An electro-cardiogram showed anomalous Q R S complexes, which were notched and nearly three times the normal duration; the P wave could not be identified. Digitalis therapy was unsuccessful, but normal rhythm was restored after 2.6 grams of quinidine had been given, and the failure quickly disappeared. Subsequent attacks were terminated by quinidine, but administration of this drug did not prevent recurrence. The abnormal rhythm was observed to be sometimes slow and sometimes rapid, the latter often succeeding the former. The intramuscular injection of atropine sulphate (1/100 grain) was found always to provoke a paroxysm of tachycardia, which in turn could be terminated by quinidine. Electro-cardiograms showed the tachycardia to be ventricular, since transitional cycles were demonstrated in which the P R interval was so short that the ventricle must have responded to its own impulse as well as to that of the auricle. The patient has been under observation for nearly five years, and the attacks have diminished in severity and frequency despite the cessation of treatment during the last nine months.

84. Peribronchial Syphilitic Sclerosis.

IN addition to the clinical syndrome occurring in chronic syphilitic bronchial catarrh, R. BENDA (*Arch. Méd.-Chir. de l'Appar. Respir.*, August, 1928, p. 283) describes an anatomical and radiological syndrome of peribronchial sclerosis, which is not less diagnostic. Syphilis has a marked affinity for the bronchi, the blood vessels being little attacked; this contrasts with its effect in other organs, such as the kidneys and liver. Syphilis can attack any part of the tracheo-broncho-alveolar tract, and the lesions vary in degree. Syphilitic sclerosis proceeds by large tracts which dissect the lobe and lobules, creep between the alveoli, and surround the bronchioles and vessels. The sclerosis forms rings, the thickness of which is directly proportional to the size of the tubes. The bronchi are either thickened or mutilated, as the sclerosis may be of two types—namely, the hypertrophic, and the mutilating or destructive. In the latter the bronchial walls are infiltrated, and, in extreme cases, are reduced to scattered particles. Though the vessels are less affected, a number of arterioles are encircled by a periarteritis. The sclerosis consists of newly formed tissue in which collagenous fibres and capillaries predominate. In places are found follicular islets, rich in plasmatocytes and young vessels which bear a strong resemblance to syphilitic gummata. Only in extensive infections does ectasis occur. On radiological examination the broncho-vascular arborizations, rendered visible by the sclerosis, appear on the screen and plates as large fan-shaped tracts, which can be followed to their ultimate endings; between these tracts the concomitant peri- and intralobular sclerosis appears as fine marblings or more or less homogeneous mottlings. These last are very limited, and the essential characteristic of the syndrome—namely, the great arborescences—remain of first importance. Calcified nodules are not found in uncomplicated syphilitic bronchitis, but abundant calcareo-sclerosis is present when tuberculosis is an associated condition. A marked diagnostic point is the presence between the broncho-vascular tracts of numerous dark rings in the parahilary regions.

85. Post-typhoid Myocarditis.

L. ENGEL (*Thèses de Nancy*, 1927–28, No. 388), who records twenty-two cases in patients aged from 17 to 80, states that post-typhoid myocarditis may occur either progressively after the acute stage of the fever or suddenly after a latent period as the result of cardiac fatigue, when it is manifested by symptoms of ventricular insufficiency of the anginal type. As a rule the condition rapidly yields to cardiac tonics, and the immediate prognosis is good in most cases when treatment is applied in time. The prognosis, however, is more serious when the symptoms develop rapidly after the acute stage. The symptoms are to be attributed to a granular degeneration of the muscle fibres or to vascular lesions chiefly involving the arterioles. In every case the lesions are much less pronounced than in diphtherial myocarditis. The author concludes that a careful examination of the heart should be made in the case of every convalescent from typhoid fever.

Surgery.

86. Complications following the Injection Treatment of Varicose Veins.

H. O. MCPHEETERS and C. O. RICE (*Journ. Amer. Med. Assoc.*, October 13th, 1928, p. 1090) assert that, though the mortality rate following the injection treatment of varicose veins is much less than with operation, the method should not be attempted by those unaware of the possible complications. The authors describe the microscopical changes which develop after the injections, and the solutions in daily use are enumerated. They think that no one solution can be considered adequate for every purpose; each solution has quite definite indications. The most dreaded complication is pulmonary embolus, and some cases have been reported of this occurrence, which, however, is very rare. Emboli are more likely to follow the injection of solutions which cause coagulation of the blood, but these are now little used. Emboli are to be feared when phlebitis is present or has recently subsided, and injections should not be made until all tenderness and signs of phlebitis have entirely disappeared. Other non-fatal complications may occur. The most common of these is the formation of a blanched ecchymotic patch or slough following the perivascular injections of sodium chloride and sodium salicylate. If an excess of the solution is injected into this area within half an hour after its appearance the reaction is terminated and the viability of the tissues is preserved. If a slough forms, excision with primary closure at the end of forty-eight hours is the best treatment. Sometimes a very painful chemical cellulitis occurs, due to osmosis through the thin wall of the vein of a certain amount of fluid. This responds quickly to heat applied locally and followed by a tight bandage. This reaction is less evident following injections with invert sugar solutions than with any other, and is much more intense and persistent with sodium chloride, sodium salicylate, and mercuric iodide or chloride.

The reaction can be definitely lessened by applying rubber sponge strips over the vein and bandaging the leg tightly. At times an ascending venitis with a firm thrombus formation occurs in the saphenous vein up to the sapheno-femoral opening. Staphylococcal infections can occur at the injection site, but these can be avoided by a careful technique. Fatalities occurring concurrently with the injections are often erroneously attributed to the treatment.

87. Treatment of Obstructed Ureteral Calculi.

By the term "mobilization" A. G. CASARIEGO (*Journ. d'Urol.*, October, 1928, p. 331) denotes the non-surgical treatment of ureteral calculi. Congenital conditions in the ureter may render it difficult to promote renal drainage, and so may predispose to the arrest of calculi; these then set up pathological changes in the ureteral walls, which may cause immobilization of the calculus and thus originate renal troubles. If the obstruction is prolonged the renal lesions become more intense, and in some cases may terminate fatally; hence the importance of mobilizing the calculi as early as possible. The form, rather than the size, of the calculus plays a great part in its arrest; irregular ones may become fixed, even though small, owing to the changes in the ureteral walls and the development of adhesions, while larger ones pass unchecked. The aim of mobilization is to re-establish renal drainage. Calculi are most often found near the ureteral opening into the bladder; at other times they can be better approached from the pelvis of the kidney. Mobilization is performed by means of ureteral sounds or fine bougies; the latter pass between the calculus and the wall, thus dilating the canal and rendering easy the descent of the calculus. In the author's practice vesical and ureteral anaesthesia with a 2 per cent. solution of novocain is induced. With the aid of a cystoscope, a special ureteral sound of variable size (in some cases a No. 10 can be used), with a cut end and whalebone in its interior, is passed. When the calculus is reached, oil is injected into the sound and thus envelops the stone. It is then repeatedly struck with the whalebone, becomes dislodged, and easily descends. By this method Casariego has obtained mobilization of calculi in cases where other measures have failed.

88. Absorbable Haemostatic Plugging.

As a haemostatic in wounds and oozing cavities in the tissues H. FERIZ (*Zentralbl. f. Chir.*, December 15th, 1928, p. 3138) has used a preparation which consists of 96.3 per cent. of centrifugalized sterile ox serum, 3.5 per cent. of sodium citrate solution 1 in 10, and 0.2 per cent. of an antiseptic quinoline derivative. The preparation is heated to about 37.5° C. in a water-bath and activated by the addition of 0.5 per cent. of a 4.5 per cent. solution of calcium chloride immediately before it is used. When this fluid is injected into oozing tissues coagulation occurs almost directly; if a wound cavity is filled with it coagulation follows in two or three minutes. If possible the tissues surrounding the oozing cavity should be compressed at the same time, or the tissues and the cavity may be injected simultaneously. It is said to be advisable to wait a few minutes before closing a wound treated in this way in order to make sure that the coagulum is not being raised from the surface of the tissues by a haematoma. Experiments on guinea-pigs have demonstrated that the coagulum thus produced is ultimately absorbed to a large extent, while the small portion which is not absorbed becomes organized. Attempts were made to use the preparation as a plate culture medium for staphylococci and other organisms, but no growth ensued. Experimental intracutaneous and subcutaneous injections of the preparation into dogs showed that incised wounds in the injected area healed as quickly as control incisions. No anaphylactic symptoms were observed after repeated injections in guinea-pigs; it is suggested that there is little risk of such occurring, since the protein constituents of the preparation are absorbed so slowly. The main advantage of the method of treatment appears to be that the coagulum can serve as an effective substitute for plugs of gauze and other non-absorbable substances in the control of haemorrhage. It has been found particularly useful in the surgery of the brain and skull, as well as after removal of the prostate, provided that in the latter case the surrounding tissues are infiltrated with the solution before the cavity is filled with it.

89. Plastic Mammectomy.

DARTIGUES (*Bull. et Mém. Soc. Chir. de Paris*, November 2nd, 1928, p. 739) describes, with photographs, an operation he practises for the removal of hypertrophied breasts with the minimum of disfigurement. The aesthetic element in his procedure consists in preservation of the nipple and areola by grafting these on to the portion of the breast left. The author finds this method gives far more satisfactory results than others he has tried. It avoids the objection that many women make to the absence of the nipple or areola after removal of the breast. In one of the author's cases the aesthetic benefit of his operation persisted up to three years.

Therapeutics.

90. Oxygen Treatment after Thyroidectomy.

W. BOOTHBY (*Svenska Läkar. Forhandl.*, November 30th, 1928, p. 244) records his observations on 59 cases of exophthalmic goitre, 27 of hyperfunctioning adenomatous goitre, 4 of adenomatous goitre without hyperthyroidism, and 1 of carcinoma of the thyroid gland, treated at the Mayo Clinic in an oxygen chamber after thyroidectomy; 67 of the patients survived and 24 died. The oxygen concentration in the chamber varied only slightly in the different cases. As a rule, oxygen was kept at a concentration of 50 to 60 per cent., but if cyanosis persisted higher concentrations were occasionally used, although possibly concentrations of more than 60 per cent. were not of any particular advantage. As the clinical condition improved the oxygen tension was gradually decreased to 30 per cent. before the patient was removed from the chamber. The most striking clinical effect in patients suffering from pulmonary oedema, bronchopneumonia, slight cyanosis, and fever was the fall of temperature following admission to the oxygen chamber. Among the survivors the average drop was 1.3° C., and among those that died 0.8° C. The most marked fall in temperature occurred in cases of pulmonary oedema and bronchopneumonia. Patients with laboured respiration from frank pneumonia, or obstruction of the upper respiratory tract from any cause, were greatly and immediately relieved by the oxygen treatment. The cyanosis was controlled at once in all cases, but in a few cases reappeared as the pneumonia progressed. Although a direct comparison of mortality rates in the treated and untreated groups was not possible, Boothby has no hesitation in concluding that the mortality from goitre during the last two years has been somewhat lower than it would have been without the use of oxygen.

91. Trypaflavine in Gonorrhoea.

M. ALVAREZ (*Arch. de med., cir. y esp.*, December 15th, 1928, p. 673) reviews the literature and records his observations on 100 cases of gonorrhoea treated by trypaflavine. Of these 68 were acute or subacute and 32 chronic cases; 9 were complicated by epididymitis, which was bilateral in one case, 7 by acute cystitis produced by intraurethral injections by the patients themselves, and 15 by prostatitis. In 35 cases urethro-vesical lavage according to Janet's method was employed with solutions of 1 in 1,200 to 1 in 5,000. In 20 instances intravenous injections exclusively were given in doses of 10 c.cm. of a 0.5 per cent. solution; 10 patients received doses of 5 c.cm. of a 2 per cent. solution, 5 were given intravenous injections of 10 c.cm. of trypaflavine and intraurethral injections of 5 per cent. argyrol daily, and 30 had both lavage and intravenous injections. Alvarez's conclusions are as follows. (1) Trypaflavine and acridine derivatives generally form a good method of treatment for gonorrhoea both in its acute and chronic form, without being specific. They should be preferred to all other methods, since they considerably shorten the acute stage and the total duration of treatment. (2) Trypaflavine constitutes the treatment of election for acute gonococcal cystitis. (3) Its use in other complications of gonorrhoea yields similar results to those obtained by the ordinary methods. (4) In chronic cases intravenous injection should be associated with suitable local treatment. (5) Intravenous injections, if administered carefully and slowly, do not give rise to any dangerous symptoms.

92. Combined Injections of Luminal and Scopolamine.

E. HEINRICI (*Deut. med. Woch.*, December 7th, 1928, p. 2056) has used a mixture of luminal and scopolamine as a sedative in a number of patients suffering from morbid excitement with hallucinations and other mental disturbances. The preparation was injected subcutaneously, the dose for most of the injections being 1.2 c.cm. of a preparation containing 0.2 gram of pure luminal and 0.001 gram of scopolamine per c.cm., while a few received 2.2 c.cm. of a mixture containing 0.4 gram of pure luminal and 0.001 gram of scopolamine in 2 c.cm. One hundred injections were administered to a total of twenty-one patients, and in nearly every case a prolonged sedative effect resulted; in most instances sovereral hours' sleep supervened in from ten to forty-five minutes after the injection. In a few cases sleep was interrupted by a period of wakefulness lasting up to two hours, but this was again followed by several hours' sleep, which was, however, never so deep that involuntary evacuation of the bladder or rectum

occurred. The injections were found effective in a number of cases in which the use of morphine and scopolamine (0.5 c.cm. of ½ per cent. solution of morphine and 0.5 c.cm. of 0.1 per cent. solution of scopolamine) or scopolamine alone (1 c.cm. of 0.1 per cent. solution) had either failed to produce a sedative action or had increased the excitement. One patient became delirious for a time after the injection, but in no other instance were undesirable local or general effects observed after injections of 1.2 c.cm., even when these were repeated. The larger (2.2 c.cm.) injections frequently resulted in a marked fall in blood pressure and weakening of the pulse, and were therefore avoided as far as possible. In cases of pure motor excitement the treatment appeared to have no advantages.

93. Ortho-iodoxybenzoic Acid in Arthritis.

A. G. YOUNG (*New England Journ. Med.*, December 13th, 1928, p. 1194) reports a clinical study of the effect of o-iodoxybenzoic acid in the treatment of arthritis, and records twenty-five cases of arthritis of unknown etiology, nine of gonorrhoeal arthritis, and ten of rheumatic infections; good results were obtained in all three types. The drug was administered by the oral, rectal, and intravenous routes, but Young considers that the best clinical results are obtained when intravenous injection is employed. When this is impossible, high rectal enemas usually give fair results, but the oral form of administration appears to be the least promising. Each patient received about six to nine doses. The author states that painful reactions can be avoided if the solution is prepared from sterile freshly distilled water. The rubber tubing of the gravity set must be kept absolutely clean, and at least ten minutes should be taken in administering the drug. It is added that ambulatory patients may be allowed to return home within half an hour to an hour after being treated.

94. Treatment of Rickets by Ergosterol.

P. ARMAND-DELILLE (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, November 29th, 1928, p. 1555) alludes to the previous communication made by Lesné, R. Clement, and S. Simon (see *Epitome*, January 5th, para. 14) to the effect that the cure of rickets by irradiated ergosterol is more rapid in children who are not living in an environment deprived of air and light. Armand-Delille also emphasizes the fact that treatment by ergosterol is the most effective means of producing recalcification in rickety bones. In order to obtain a cure of the hypotonus of the striated and smooth muscles characteristic of rickets there is need not only of artificial ultra-violet rays, but also of sunlight; this probably acts by stimulating the action of a series of vitamins distinct from vitamin D, which is concerned in the fixation of calcium.

Dermatology.

95. Dermatitis due to Rhus toxicodendron.

A. GIUSEPPE (*Rif. Med.*, October 15th, 1928, p. 1344) discusses allergic phenomena caused by the *Rhus toxicodendron* (North American poison ivy). This shrub was brought to Europe from America in 1622, and has long been recognized as toxic to certain individuals (see *Journal*, 1924, vol. i, pp. 506 and 1112). The author reports the case of a man, aged 56, who had been a gardener in the botanical gardens at Padua for thirty-three years. At his first contact with the plant he developed toxic symptoms. To susceptible persons all parts of the plant—root, stems, and leaves—whether fresh, or dried even for a long time, were poisonous, especially when the plant was flowering. The clinical manifestations appeared from two to ten days after direct contact. In the acute stage a papulo-vesicular eczema appeared on the hands (interdigital spaces and wrists), face, neck, and scrotum. This was accompanied by severe symptoms of general poisoning. Histologically there was nothing characteristic. One attack of dermatitis did not confer immunity, although, according to McNair, there is apparently a relative immunity, as instanced by the fact that among eighteen patients with acute or chronic urticaria of other forms only one manifested a sensibility to *Rhus toxicodendron*. An alcoholic extract of part of the fresh plant provoked a typical reaction even in a dilution of 1 in 100,000. The entire skin and mucous surfaces were sensitive. The severity of the reaction depended on the thickness of the corneal layer. An attempt to transmit hypersensitiveness from man to man or man to animal did not succeed. Apparently the serum of the hypersensitive contained no antibody capable of neutralizing the entire toxin, and there was nothing comparable with the Bordet-Gengou reaction. The idiosyncrasy depended on the sensitiveness of the skin. In the latent period there might be an antigen-antibody reaction between the cells of the skin and the toxin. The gardener showed hypersensibility to the first contact with *Rhus toxicodendron*, but no predisposition to eczema was recorded in any of his relations or ancestors. It was considered that the allergic symptoms displayed by susceptible individuals were due to some unknown constitutional condition.

96. Hereditary Dystrophy of the Nails.

H. B. THOMPSON (*Journ. Amer. Med. Assoc.*, November 17th, 1928, p. 1547) reports a case of hereditary dystrophy of the nails in a girl, aged 5, who otherwise seemed to be perfectly healthy. The bases of the nails appeared to be normal, but they increased in thickness towards the distal ends and were very brittle and dry. Apparently they grew in thickness at the expense of length; occasionally one or more nails became infected, loosened, and separated in one piece without much soreness; the new nail gradually repeated this process. The author illustrates in a chart the inheritance of this condition by his patient, and records that, of thirteen children born to the original pair, five were affected—four males and one female. In the next generation, out of twenty-six offspring, five were again affected—four males and one female. In the last generation, including the present patient, four were affected out of twenty-five offspring—two males and two females. In all cases save one the dystrophy was inherited directly from an affected parent; the exception had normal unaffected parents and grandparents. Thompson points out that the ratio of affected progeny to the total number appears to diminish gradually in each generation, as does also the severity of the condition. Treatment by *x*-ray applications was employed, divided doses of unfiltered radiation being given up to the point of commencing erythema. Following this treatment a definite line developed from the base, gradually growing outward with the nail; the portion behind this line appeared to be much thinner and more nearly normal. The author proposes to use thyroid therapy in conjunction with *x*-ray treatment in these cases, but he is not very sanguine as to the probable permanence of the results.

97. Pityriasis Rubra.

R. E. BARNEY (*Arch. Derm. and Syph.*, November, 1928, p. 716), from an analysis of cases reported in the literature as pityriasis rubra of Hebra, concludes that they can be classified in five groups, since with similar clinical pictures they present diverse pathological and etiological differences. The first group consists of cases associated with active tuberculosis, and represents the cutaneous manifestation of visceral and glandular affection. The second group, which includes the types of scaly erythroderma, is allied with the lymphoblastomas, and includes leukaemia, Hodgkin's disease, lymphosarcoma, and the initial stage of granuloma fungoides. A third group comprises cases secondary to underlying dermatoses, such as eczema and psoriasis, and in the fourth group are cases suggestive of other disease entities; the fifth group contains cases of chronic exfoliative dermatitis of obscure origin owing to lack of microscopic and post-mortem observations. Barney emphasizes the importance in all chronic cases of exfoliative dermatitis of repeated investigations of the blood and skin, and urges the above group reclassification in place of the name "pityriasis rubra of Hebra."

Obstetrics and Gynaecology.

98. Ovarian Cysts and Pregnancy.

E. FORGUE (*Paris Méd.*, December 15th, 1928, p. 527) remarks that when an ovarian cyst is associated with pregnancy the question arises of its treatment during gestation, labour, and the puerperium. The degree of diagnostic difficulty varies in the different stages of pregnancy: at the commencement recognition of the coexistence of the two conditions is difficult, while in the later stages of pregnancy the presence of a concomitant cyst becomes obscure. These difficulties are especially noteworthy when the cyst is large and develops in the abdomen, and when it is small and evolves in the pelvis. Conditions requiring differential diagnosis are uterine malpositions and fibromas, ectopic gestation, and, in cases of right ovarian cysts, acute appendicitis. The effect of a cyst on pregnancy depends on its size, position, nature, and origin (abdominal or pelvic). A large cyst causes abortion or premature labour in nearly a fifth of the cases. When the cyst and uterus rise into the abdomen and do not obstruct each other, pregnancy can proceed uninterruptedly. A large cyst may push back the uterus into an abnormal position, thus causing troubles in accommodation and engagement, and, by pressure on the bladder, diaphragm, and circulation, give rise to dysuria, dyspnoea, oedema, and ascites. A small pelvic cyst does not hinder uterine development, though it becomes

an obstacle to natural delivery. The most dangerous effect of pregnancy on the cyst is pedicular torsion of the tumour. Forgue maintains that all ovarian cysts detected during the first part of pregnancy should be removed as soon as possible, in both the maternal and foetal interests. During the second part of pregnancy, especially from the seventh month, if the tumour is well tolerated, only a watchful, expectant treatment is advised. During labour, when dystocic cysts are present, the treatment of choice, if conditions are favourable, is abdominal ovariotomy followed by natural delivery. If conditions are unsuitable for this, the cyst should be either replaced or reduced in size by puncture or incision. If cystic complications, such as torsion, suppuration, or intracystic haemorrhage, occur during the puerperium, immediate surgical intervention becomes necessary; in the absence of these, ablation of the cyst can be deferred till the end of the puerperal period.

99. Aspiration of the Uterus in Chronic Metritis.

In order to obtain satisfactory drainage of the uterus and the cervix in cases of chronic metritis, E. VILLARD and O. MANTELIN (*Lyon Méd.*, November 18th, 1928, p. 581) have devised a special apparatus which consists of a glass speculum of the Fergusson type to which can be attached an aspiratory pump. The mouth of the speculum is closed by a rubber cork, through which passes a small piece of glass tube; this is connected by rubber tubing with a flask. A manometer is attached laterally to regulate the pressure, and a decompression tap is also attached to the speculum. The patient is placed in the gynaecological position and the speculum inserted in the ordinary way. A negative pressure is produced amounting to about 15 cm. of mercury, the manometer readings being carefully watched and also the patient's reactions. At the first treatment patients complain of twinges in the pelvis and lumbar region. Each treatment lasts about five minutes; at the end of that time the pressure is slowly brought back to the normal, when the cervix is seen to be bathed in a more or less abundant muco-purulent secretion. Ten to twenty treatments are given, at first twice weekly and then weekly. The results were in general satisfactory. The secretion became clean and less in quantity after four or five treatments. There was also a remarkable diminution of the pains complained of by the patient.

100. The Decidual Reaction in Tubal Pregnancy.

A. R. MORITZ and MARION DOUGLASS (*Surg., Gynecol. and Obstet.*, December, 1928, p. 785) have studied the uterine and tubal decidual reaction in tubal pregnancy, making histological examinations of the tubes and endometria in fifty-three cases of ectopic gestation in order to determine the frequency of the occurrence of uterine and tubal decidua in such cases, as well as the frequency of vaginal bleeding and its relation to the state of the chorionic villi, endometrium, and embryo. In only eight instances was uterine decidua detected; when it is present it is to be found at the implantation site if the chorionic villi are intact. Vaginal bleeding was a common symptom, but it was not necessarily associated with the death of the foetus, the condition of the chorionic villi, or the physiological state of the endometrium. In four cases the foetus was found at operation to be in excellent preservation or living, but only two of these showed a decidual reaction in the uterus, and in each instance where the foetus was dead the vaginal bleeding had been present prior to the possible date of foetal death, showing thereby that such bleeding does not invariably indicate foetal death. The authors' conclusions agree with those of B. S. Kline, who stated that the tubal decidual reaction persisted as long as the chorionic villi were intact.

101. Danger of Curetting in Uterine Cancer.

VICTOR-PAUCHET (*Bull. et Mém. Soc. Chir. de Paris*, November 2nd, 1928, p. 726) reports a case which illustrates the danger of diagnostic curettage in cancer of the body of the uterus. A woman, aged 60, was curetted for diagnostic purposes, and during the operation the uterus was perforated. The perforation healed spontaneously, but a year later laparotomy was performed and fungating cancer was found in the site of the perforation, involving the small intestine. Hysterectomy and enterectomy were performed. Six months later metastases occurred in the great omentum. It has been pointed out how easy it is to perforate in this class of case, and many authorities consider that laparotomy in these cases is less dangerous than curetting and more satisfactory in diagnosis. When perforation occurs it is safest to proceed as soon as possible to laparotomy. Cases have been reported where perforation had been caused by the introduction of radium.

Pathology.

102. Fowl Tuberculosis in Man.

E. LÖWENSTEIN (*Med. Klinik*, November 16th, 1928, p. 1783) describes a form of tuberculosis occurring in fowls which is transferable to cattle and pigs, and is found widely distributed in the poultry farms, stock farms, and slaughterhouses of America. It also infects man. The infection is conveyed usually by food contaminated with fowl dung. Cases are reported of direct skin infection of farm employees working with bare feet. The disease in man is epidemic, and clinically a septicaemia like paratyphoid fever. The illness starts with a prolonged period of intermittent fever uninfluenced by antipyretics, associated with enlarged spleen, and followed by pyaemic-like metastases in the bone marrow, liver, and kidneys, in which are found masses of acid-fast bacilli. The bone marrow infection is accompanied by an increase in the number of red blood cells and white cells, and sometimes is associated with myelogenous leukaemia, in which case the enlarged spleen does not react to *x*-ray treatment. The lungs are not usually attacked. In fowls the bacilli are found chiefly in the mesenteric glands, bowel, ovary, and cloaca. The organism is characterized by quick growth on most artificial media, especially in glycerin broth. Most strains have a slight pathogenicity for guinea-pigs, which almost completely disappears after several subcutaneous passages. Rabbits and fowls are susceptible in varying degrees to intravenous injection. In man the disease does not react to old tuberculin, but reacts strongly up to 1 in 50,000 dilution to a specific fowl tuberculin. Fowl tuberculin gives no reaction in persons infected with mammalian tuberculosis.

103. The Serological Races of Clostridium welchii (B. perfringens).

MLLE A. HOWARD (*Ann. de l'Inst. Pasteur*, November, 1928, p. 1403) has made a serological study of sixty strains of *Cl. welchii* recovered from various sources. She prepared agglutinating antiserums to fifteen of them, and then tested these serums against all the strains. The best method of preparing the serums was found to be the injection of rabbits at three-day intervals with large and increasing doses of organisms obtained by centrifugalization of a twenty-four-hour glucose broth culture. In this way fairly high titre serums were obtained within four weeks. No definite serological grouping could be demonstrated. Most of the strains agglutinated with one or more—sometimes all—of the serums; four of the strains, however, were agglutinated solely by their homologous serums, though the serums prepared against them were able to agglutinate several of the other strains. Biochemical grouping by means of the glycerin and inulin fermentation tests was conducted, as originally recommended by Simonds, and a distribution was found not unlike that recorded by Simonds; but attempts to relate the biochemical to the serological grouping proved hopeless. A serum, for example, prepared against a strain which did not attack inulin agglutinated strongly a strain which did ferment inulin, and so on. The present author concludes that most strains of *Cl. welchii* show an evident relation to one another, but that no relation exists between the serological types and the biochemical types.

104. The Synovial Fluid in Chronic Arthritis.

C. E. FORKNER, A. R. SHANDS, and MARY A. POSTON (*Arch. Intern. Med.*, November, 1928, p. 675) report an attempt to correlate the bacteriology and cytology of synovial fluid in chronic arthritis and to ascertain whether any difference exists between the cytological observations in sterile synovial fluid and in that showing positive bacterial cultures. Sixty-three cases were studied, of which fifty-two were of the infectious type, nine of the hypertrophic type, and two of the infectious and hypertrophic type. Bacteriologically it was found that positive cultures could be obtained from the joint fluids and regional lymph nodes in a fair percentage of cases of chronic arthritis of non-tuberculous and non-syphilitic origin, and in positive cases repeated positive cultures could be obtained from the same or similarly involved joints. The coincidence of isolating the same organism from both the lymph nodes and the joints points to these organisms being the causative agents of the arthritis. In all the cases the white cell counts in the synovial fluid were increased, and the average count in the bacteriologically positive cases was approximately double that in the negative cases. The number of polymorphonuclear neutrophils was higher in the group giving positive cultures from the joint fluid, while the number of monocytes and lymphocytes was higher in the group giving negative cultures.

"CIBA" BRAND

OVARIAN PREPARATIONS OF SPECIAL IMPORTANCE

STANDARDISED OVARIAN HORMONE

SISTOMENSIN

Indicated in Dysmenorrhœa, Menorrhagia, Menopause (natural and artificial), Hypoplasia of the Uterus, Infantilism, Sterility, etc.

Ampoules and Tablets.

HYDROSOLUBLE OVARIAN SUBSTANCE

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

Fifth International Congress of
Military Medicine and Pharmacy.

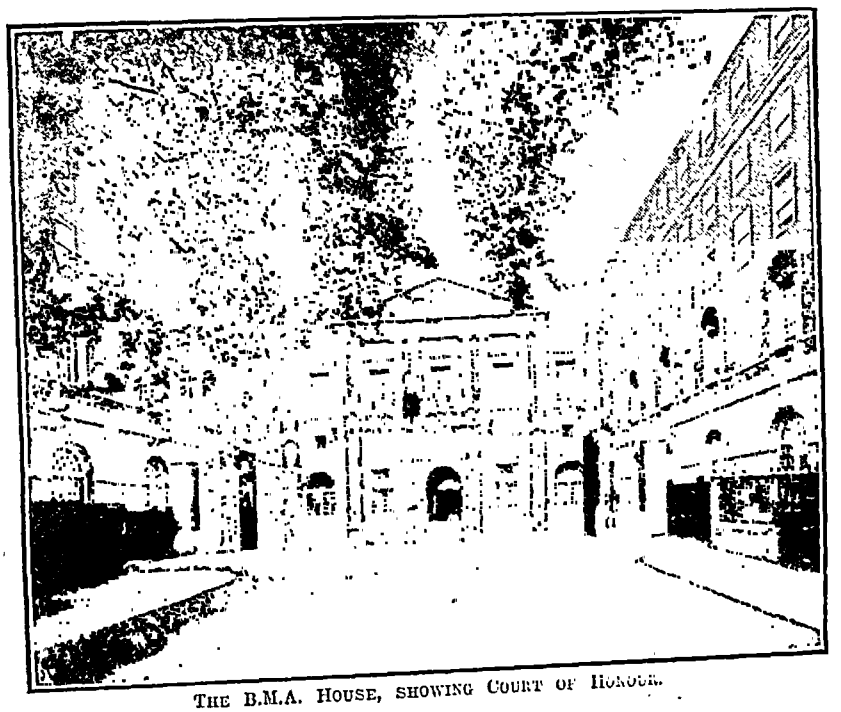
MAJOR A. D. STIRLING, D.S.O., R.A.M.C., *Secretary.*
L. FERRIS-SCOTT, F.C.A., *Exhibition Manager.*

MONDAY, MAY 6th, to FRIDAY, MAY 10th (inclusive), 1929.

An
EXHIBITION
of
SURGICAL INSTRUMENTS AND APPLIANCES, DRUGS, FOODS, BOOKS, &c.,

will be held in the

British Medical Association House



Tavistock Square, London, W.C.1.

THE B.M.A. HOUSE, SHOWING COURT OF HONOUR.

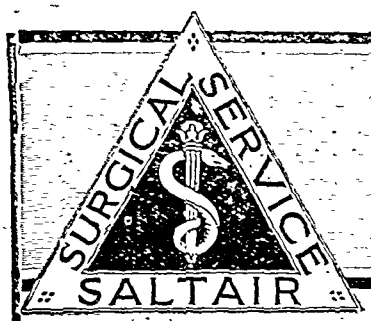
The Exhibition will be open for inspection from 2 p.m. to 6 p.m. on **Monday, May 6th,** and will remain open from 9 a.m. to 6 p.m. on **Tuesday, Wednesday, Thursday,** and **Friday, May 7th, 8th, 9th,** and **10th.**

Many attractive functions and ceremonies will be held in the B.M.A. House in connection with the Congress, which will be attended by about 800 delegates from some fifty different countries.

All members of the British Medical Association in the Metropolitan area, to the number of 4,500, will receive individual invitations to the Exhibition, and all medical men are invited.

For particulars of Space available for Exhibits,

Apply to: **L. Ferris-Scott, F.C.A.,** BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.



SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

The Difference

The Stock Truss can be adapted by bending the spring—but, if the spring is weak enough to be bent when cold, its shape and strength will vary each time it is applied, with consequent loss of fit.

SALTS' TRUSS is made to measure only (according to the Practitioner's prescription) and is provided with a specially heat-tempered spring that never deviates from the exact "lie" and spring pressure necessary for the check of further Hernial development.

No matter how often SALTS' TRUSS is taken off, it maintains Correct Pad Pressure.

It costs NO more to let SALTS make a truss for your patient, and you **know** that your prescription will be faithfully fulfilled in every detail.

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

COPYRIGHT

ESTABLISHED 1793.

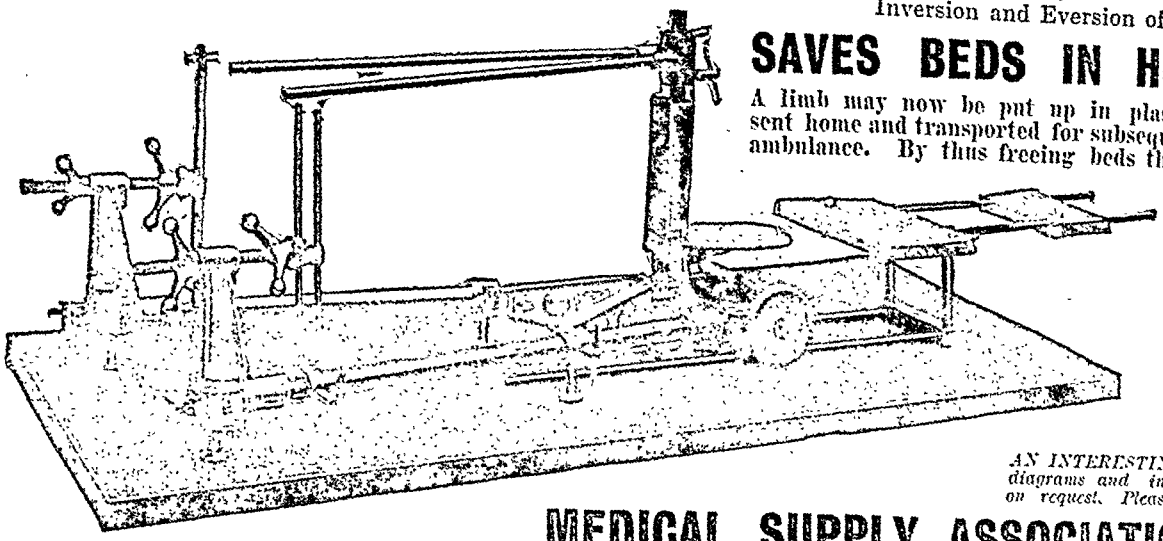
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 32 in. × 11 in. × 7 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

ULTRA-VIOLET IRRADIATION

THE value of irradiated milk for rachitic children and in cases of tuberculosis of the bones has been shown many times. (See *B.M.J.*, March 28th, 1925; *The Lancet*, Jan. 2nd and Dec. 25th, 1926; *The British Journal of Radiology*, Feb., 1926; and the *Journal of Actinotherapy*, June, 1928). But hitherto the process of irradiation has always tainted the final product.

This difficulty has now been overcome by the

"SCHEIDT" PROCESS

in which COLD QUARTZ TUBES

with remarkable U.V. Spectra give an easily controlled and positive activation and leave the products

"BANISH TRUSS TORTURE"

AND SECURE ACCURATE ABDOMINAL SUPPORT AND COMFORT FOR YOUR PATIENTS BY RECOMMENDING THE

"ROSE CORSET-BELT"

which has proved so effectual in all abdominal cases. The X-ray has shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

WRIGHT'S LYSOL

A handy graduated measure is provided with every bottle.

"LYSOL"—Your patients must always qualify the word.

To ask merely for "Lysol" is dangerous, for they may be given an inferior Lysol that will actually do far more harm than good. Tell them, *for their own safety, to insist on Wright's Lysol.* It gives sure results—always. It is perfectly pure, non-caustic, and causes no irritation. British owned and made under the strict Rideal-Walker control test by the makers of the world-renowned Wright's Coal Tar Soap—Producers of Disinfectants for over sixty years.

Tell your patients to say "Wright's" before saying "Lysol." That way lies certain safety and protection.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases.
Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289

NEURASTHENIA,
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, Ultra-Violet Light, and Massage is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week. *For further particulars apply to*—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: *Shardlow* 16.
Dr Douglas-Morris can be seen by appointment in London.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent

MAUDSLEY HOSPITAL,
DENMARK HILL, S.E.5.

Telephone: BRIXTON 788.

NATIONAL SUN-RAY AND HEALTH CENTRES LTD.

845/850, SALISBURY HOUSE, LONDON WALL, E.C.2.

The Board of Directors of the above Company desire to make known to the Medical Profession their decision to cease all advertisements to the Lay Public and to conduct their Centres in strict accordance with the recognised principles of the Medical Profession.

Each of their Centres will be under the control of whole-time qualified, registered medical practitioners, assisted by a staff of trained male and female operators.

The Directors desire medical practitioners to realise that they may refer such of their patients as, in their opinion, are likely to benefit by Actino-therapy and other Physio-therapeutic measures, to these Centres with every confidence.

The Medical Officer at each Centre will at all times be pleased to see any local practitioners who may wish to satisfy themselves as to the nature of the provision made for their patients' treatment and comfort.

Interested Practitioners should write to the Head Office for Literature, or to the Ealing Treatment Centre, 23a, The Broadway, Ealing, London, W.5. Telephone: Ealing 2843.

The Chadwick Trustees invite

application for TWO TRAVELLING SCHOLARSHIPS of £400 a year each, tenable for one year, to be awarded next July; one Scholarship to be in SANITARY SCIENCE, and the other in MUNICIPAL ENGINEERING.

The object of the Scholarships is to enable the holder to travel abroad to study, either generally or in some particular aspect, the methods adopted in different countries for the prevention of disease and the improvement of the public health, or the sanitary administration and engineering applied in urban or rural areas.

Candidates must be British subjects, between 25 and 30 years of age, who have graduated in a British University, or who can produce evidence of attainments or of intellectual equipment proving them to be capable of methodical study and research.

A candidate prior to appointment must submit for the approval of the Trustees a scheme of study which he would be prepared to undertake and the itinerary he would propose to follow.

He would be required upon his election to undertake to conform to any plan approved by the Trustees, and from time to time and at the termination of his Scholarship to furnish reports to the Trustees on the results of his investigations in the course of his tour, which reports may be printed and published at the expense of the Trustees, who may require to retain the copyrights.

No other Scholarship shall be held nor any remunerative employment be undertaken during the tenancy of the Chadwick Travelling Scholarship without the express sanction of the Trustees.

The award of the Scholarships, and the acceptance or refusal of any applications, are entirely at the discretion of the Trustees, who may also, at their discretion, renew a Scholarship for a year.

Applications should be made by letter to the Clerk of the Chadwick Trustees, at 204, Abbey House, Westminster, S.W.1, stating name, qualifications, age, and proposed object of study or research, accompanied by copies of testimonials and evidence of previous work undertaken or published.

January, 1929.

University of London.

Swansea County Borough.

RESIDENT MEDICAL OFFICER.

INFECTIOUS DISEASES HOSPITAL.

The Council invite applications for the above appointment from duly qualified unmarried medical practitioners. The salary will be at the rate of £350 per annum, together with emoluments. Previous experience in an Infectious Disease Hospital is desirable.

Applications (on special forms with particulars of duties, can be obtained from the Medical Officer of Health, Public Health Offices, Swansea) to be sent in not later than February 13th.

[AMENDED NOTICE]

University of Cape Town.

ASSISTANT IN PATHOLOGICAL CHEMISTRY.

Applications are invited for an Assistant in Pathological Chemistry, who will be required also to undertake research in the Department of Pathology.

The Assistant must have a registrable Medical qualification and special knowledge of Chemical Pathology. The duties will include teaching of Pathological Chemistry and Biochemical work for the Hospital. The Assistant must engage in research work in the Department of Pathology, and time for such work will be available.

Salary.—£800 per annum, but for pension purposes it will be regarded as being on the scale £500—25—650. The Assistant must become a member of the University Teachers' Superannuation Fund. Salary commences from date of assumption of duty.

Transport.—£50 will be allowed for transport expenses, subject to a proportionate refund in the event of the Assistant terminating his agreement within 3 years of the assumption of duty.

Candidates must state the earliest date on which they will be able to assume duty.

Applications, together with copies of testimonials (all in quadruplicate) should reach the Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2, from whom forms of application and further particulars may be obtained, not later than the 26th February, 1929.

University of Melbourne,

VICTORIA, AUSTRALIA.

CHAIR OF OBSTETRICS.

Applications are invited for the above Chair. Salary £2,000 per annum. For particulars apply to the Agent-General for Victoria, Victoria House, Melbourne Place, Strand, London, W.C 2, with whom applications must be lodged on or before March 31st.

States of the Island of Jersey.

COMMITTEE FOR THE JERSEY MENTAL HOSPITAL.

MEDICAL SUPERINTENDENT.

This office being vacant, the States will proceed next month to appoint a Medical Superintendent for the above establishment, who will be required to enter upon his duties about the end of February or beginning of March next.

The appointment is for three years, at a salary of £650 per annum, with house (and garden) in which the person appointed will be required to reside. The Medical Superintendent must devote the whole of his time to the duties of his office. Candidates must be Members or Licentiates of one of the Faculties of Medicine and Surgery of Great Britain or Ireland.

Sealed applications, stating qualifications, with testimonials, to be sent on or before February 9th, addressed to the President of the Committee for the Jersey Mental Hospital, Greffe Office, Jersey.

Greffe Office, Jersey. ERNEST LE SUEUR,
January 18th, 1929. Greffier.

BIO-CHEMIST AT THE BOARD'S ANTITOXIN ESTABLISHMENT.

The Board invite applications for the appointment of BIO-CHEMIST at their Antitoxin Establishment. The Laboratories and Stables are at Sutton, Surrey.

The candidate appointed will be required to assist generally in the work of the laboratories, especially with the chemical side of the work, such as the concentration of toxin and antitoxin, preparation of media, etc.; to make himself acquainted with the general running of the laboratories, and so be in a position to take charge, if required; and to conduct researches bearing especially on bio-chemical problems, subject to the approval of the Director.

Evidence of previous research work in biochemistry is desirable, and, although it is not essential that the candidate appointed should already be equipped with a special experience of bacteriology and serology, he will be expected to acquire knowledge of the current laboratory work on these subjects, with a view to the co-ordination of bacteriological and biochemical interests.

The commencing salary is at the rate of £600 per annum.

Application form containing full particulars of the appointment may be obtained by forwarding stamped addressed foolscap envelope to the Clerk, Metropolitan Asylums Board, Victoria [illegible] London, E.C.4, to whom completed [illegible] urned not later than [illegible] bruary 6th.

Clerk to the Board.

County Council of Durham.

EDUCATION DEPARTMENT.

ASSISTANT SCHOOL MEDICAL OFFICER.

The County Education Committee invite applications from duly qualified men for the post of Assistant Medical Officer to act under the School Medical Officer in connection with the Inspection of School Children, and such other duties as may be required by the Education Committee. Commencing salary £600 per annum (provided the candidate has had not less than three years' post-graduate experience), rising by annual increments of £25 to £650 per annum, together with travelling expenses according to the County scale. The successful candidate will be required to devote his whole time to the duties of the office, and reside in or near the district to which he will be attached at a place to be approved by the Education Committee The appointment will be subject to three calendar months' notice on either side, such notice to date from the last day of any calendar month. Applicants must have had experience in the work of school medical inspection, and preference will be given to candidates who:

(*a*) Have had experience in the work of School Clinics;

(*b*) Have been accustomed to make special reports on Mentally Defective, Physically Defective, Epileptic, and other Defective Children.

The possession of a Diploma in Public Health is desirable, though not essential.

Copies of not more than three testimonials are required.

Canvassing, directly or indirectly, is prohibited and will disqualify.

A deduction of 5 per cent. will be made from the salary in accordance with the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the County Council's medical examination in connection therewith

Forms of application, to be returned not later than Saturday, February 9th, may be obtained from the Director of Education, Shire Hall, Durham, on receipt of stamped addressed envelope.

Shire Hall, Durham. A. J. DAWSON, Director of Education

January 19th, 1929.

City of Birmingham.

VISITING SURGEONS.

The Public Health Committee propose to appoint Two General Operating Surgeons, practising exclusively as such in Birmingham, to carry out between them all surgical work, consultative or operative, for which their services may be requested by the Medical Superintendent of the CITY HOSPITAL FOR INFECTIOUS DISEASES, LITTLE BROMWICH. It is suggested that the two Surgeons appointed should take alternate duty. An honorarium of £200 each per annum is offered. As the scheme is experimental, it will be reviewed by the Committee at the end of a year. Any further details will be furnished by the Medical Superintendent, to whom applications, endorsed "Visiting Surgeon," should be forwarded on or before Saturday, February 9th.

City of Birmingham.

FOURTH ASSISTANT MEDICAL OFFICER required at the CITY HOSPITAL FOR INFECTIOUS DISEASES, LITTLE BROMWICH. Previous resident hospital post essential. The appointment will be made for 12 months only. Duty to commence on April 1st.

Salary £300 per annum, together with board, residence, and laundry.

Forms of application may be obtained from the Medical Superintendent, and should be returned to him on or before Saturday, February 9th.

Preston Union.

Applications are invited for the post of JUNIOR RESIDENT MEDICAL OFFICER.

Salary at the rate of £104 per annum, with board, lodging, etc.

Candidates must be duly qualified and registered under the Medical Acts.

The appointment is for six months commencing on March 1st.

Duties include work in any Wards of the Hospital, in the Institution as required, and also in the Sharoe Green Maternity Home adjoining.

Applications should be made by letter, accompanied by copies of three testimonials of recent date, and should reach me on or before 10 o'clock a.m. on Tuesday, February 5th.

Union Offices, Lancaster Road, Preston. THOMAS H. BENTHAM, Clerk to the Guardians. January 16th, 1929.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A Whole-time ASTHMA RESEARCH SCHOLAR is required on February 21st, in the Asthma Clinic established at this Hospital, under the Halley Stewart Trust of the Asthma Research Council, for special research work in the causation and treatment of Asthma and kindred complaints in children.

Gentlemen are invited to send in their applications addressed to the Secretary, with copies of not more than three testimonials, written specially for the purpose, before 12 o'clock on Monday, February 18th.

The appointment is non-resident, and is made for one year, but may be held, subject to re-election annually, for a period of four years.

Candidates must possess a legal qualification to practise.

Salary £300 per annum, with luncheon and tea provided by the Hospital when on duty.

All candidates must be in attendance on Wednesday, February 20th, at 4.45 p.m. precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the rules may be obtained from the Secretary at the Hospital.

By Order of the Board of Management,
JAMES McKAY.
January, 1929. Secretary.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A CASUALTY OFFICER is required on February 21st.

Gentlemen must be registered medical practitioners, and are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, February 18th, accompanied by copies of not more than three testimonials, written specially for the purpose.

The appointment is made for one year, but may be held, subject to re-election annually, for a period of three years.

The appointment is non-resident, and wholetime.

Salary £400 per annum, with luncheon and tea provided, and allowance of 24 guineas for substitute for annual holiday of four weeks.

All candidates must appear before the Joint Committee at their meeting on Wednesday, February 20th, at 4.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary, at the Hospital.

By Order of the Board of Management,
JAMES McKAY.
January, 1929. Secretary.

Rochford Union.
MALE ASSISTANT RESIDENT MEDICAL OFFICER.

The Guardians of the above-named Union invite applications for the appointment of Male Assistant Resident Medical Officer at the POOR LAW HOSPITAL, ROCHFORD.

The appointment will in the first instance be for twelve months and the salary at the rate of £300 per annum, with increase to £350 per annum in the event of the Officer being reappointed after twelve months' service, together with an allowance at the rate of £200 per annum in lieu of residential emoluments. The salary and value of emoluments are subject to deductions under the Poor Law Officers Superannuation Act.

Applicants must be fully qualified and have had at least two years' resident Hospital experience.

Application forms, which must be properly filled in and returned to me not later than Wednesday, February 6th, together with particulars of the duties, can be obtained from the undersigned upon receipt of a stamped addressed foolscap envelope.

By Order,
W. HARDING ROBERTS,
27, Victoria Avenue, Clerk.
South-end-on-Sea.

County Mental Hospital,
STAFFORD.

SECOND ASSISTANT MEDICAL OFFICER, male, single, required. Salary £600, rising by £25 per annum to £700; £50 per annum in addition if or when in possession of Diploma in Psychological Medicine. £130 per annum will be charged for furnished quarters, board, laundry, and attendance.

Candidates with good knowledge and experience of pathology preferred. Every opportunity afforded for study and research, serodiagnosis, etc., in well-equipped laboratory.

Appointment subject to conditions of Asylums Officers Superannuation Act, 1909.

Applications, stating age, qualifications, and enclosing copies of recent testimonials, to be addressed to the Medical Superintendent.

Borough of Leyton.
ASSISTANT MEDICAL OFFICER (Female).

Applications are invited for the appointment of Assistant Medical Officer.

Age not to exceed 45.

The inclusive salary will be at the rate of £600 per annum.

The duties will be principally in connection with maternity and child welfare and school medical services.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the approval of the Minister of Health.

Applications must be made on prescribed forms, which can be obtained by sending a stamped, addressed envelope to the undersigned.

Applications, endorsed "Assistant Medical Officer," accompanied by copies of not more than three testimonials of recent date, must reach me not later than the 31st instant.

Canvassing, directly or indirectly, will be a disqualification.

Town Hall, JNO. ATKINSON,
Leyton, E.10. Town Clerk.
January 18th, 1929.

County Borough of Southampton
APPOINTMENT OF SCHOOL DENTIST.

Applications are invited for the position of an Assistant School Dentist to carry out the Dental Examination, Treatment, etc., of Elementary School Children.

The gentleman appointed must be fully qualified and registered. He will hold office during the pleasure of the Council, and will be required to devote the whole of his time to the duties of the office and to act under the administrative direction of the School Medical Officer.

Salary £450 per annum.

The Local Government and Other Officers Superannuation Act, 1922, will be applicable to the appointment, and contributions to the Superannuation Fund will be deducted from the salary. The selected candidate will be required to pass a satisfactory medical examination.

Forms of application may be obtained of the Medical Officer of Health, Municipal Offices, Southampton.

Applications on the prescribed form, endorsed "School Dentist," together with copies of not more than three recent testimonials, must be delivered at the Town Clerk's Office on or before February 2nd.

R. R. LINTHORNE,

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3545 (5 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. DEATH VACANCY.—LONDON, N.W.—In a populous district, a well-established PRACTICE offering considerable scope, as late Incumbent was advanced in years, is for immediate disposal. Income about £500 p.a., including panel of 330. Patients middle and working-class. Visits 3/6. No midwifery. House contains consulting and waiting rooms, sitting room, 3 bedrooms, bathroom, etc.; rent £63 p.a. on lease. Premium £500.
2. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
3. SOUTH-WEST OF ENGLAND.—INLAND SPA.—PARTNERSHIP.—A half share (with succession to the whole in about 12 months' time) is for disposal in a chiefly upper and middle-class non-panel Practice, held by the Vendor for the past 30 years. Average gross cash receipts for past three years £1,233. There is considerable scope for increase, as owing to ill health much work has been refused. Fees 5/- to 21/-. No midwifery. Suitable house can be obtained. Premium £1,100.
4. SOUTH-EAST OF ENGLAND.—COAST TOWN.—Small but increasing PRACTICE, at present producing about £500 per annum, with good scope. Panel of 420. Suitable house available. Rent £52 p.a. Premium £750, part down, and balance by instalments.
5. LONDON, S.W.—RESIDENTIAL SUBURB.—Small PRACTICE, offering scope for increase. Gross cash receipts for immediate past 12 months £706, including panel of 153. Fees 3/6, 5/- upwards. Midwifery 5 guineas. Small compact house, on main road, with 2 reception, 4 bedrooms, etc. Price £1,150, payable £400 down and balance by yearly instalments of £85. Premium for quick sale £1,000, to include drugs, fittings, fixtures, etc.
6. PARTNERSHIP.—The third share of a very old-established mixed-class Practice, in a pleasant London suburb, is for disposal owing to the retirement (through ill health) of the Junior partner. Held 24 years by remaining. Cash receipts average about £2,700 p.a., including appts. producing £340 and panel of 1,000. Visits 3/6 to 21/-. Good house available, with ample accommodation. Rent £85 on lease. Premium 2 years' purchase. Excellent scope.
7. KENT.—GROWING DISTRICT, within 15 miles of London.—PARTNERSHIP.—A one-half share is for disposal in a very sound chiefly better and middle-class Practice, established many years, and held by the remaining partner over 4 years. Gross cash receipts for the past three years £2,528, including panel of 900. No appointments. Fees from 5/- to 21/-. Midwifery 5 to 30 guineas (about 25 cases yearly). Very suitable modern house, with 2 reception, 4 bedrooms, good bathroom, etc. Consulting room. Electric light. Small garden. Garage. Price for freehold about £2,100, nearly all of which could remain on mortgage. Good sport and schools, and excellent social facilities. Premium 2 years' purchase.
8. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 3/6 to 21/-, medicine extra. Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium 1½ years' purchase.
9. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, rooms garden, and usual offices. Hot water supply, Price with tennis court. Garage for two cars. for freehold £3,100. Premium 1½ years' purchase.
10. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,600. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.
11. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share (to commence with) is for disposal, owing to the retirement of the senior partner, in sound middle-class Practice, situated in rapidly developing district. Income for the immediate past year £2,124. Consultations 3/6 to 10/6, visits 4/6 to 21/-. Good freehold house, price £1,500; or would be rented on lease at £90 p.a. Low expenses. Premium 2 years' purchase.
12. OUTLYING WESTERN SUBURB.—Old-established mixed general PRACTICE. Income for the immediate past year about £2,300, including panel of between 1,400 and 1,500. Fees 3/6 to 10/6. Midwifery from 3 gns. The district is rapidly developing and there is great scope. Good house, with garden and garage. Price £2,000. Premium £3,500.
13. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appts. worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly. Moderate expenses. Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Price for freehold £1,500. Premium £4,500.
14. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, producing for the last twelve months about £700, and rapidly increasing. Panel of 150. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery, 2 gns. upwards. Good house in excellent repair, with 2 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300. Premium £1,400.
15. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, situated in good hunting centre. Gross cash receipts for past 12 months about £1,000 p.a., including panel of 600. Advice and medicine from 3/6, visits 5/6 upwards, with medicine extra. Lowest midwifery 2½ gns. Exceptionally attractive house, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1½ acres, and 12 acres of grassland. Recently re-decorated throughout. Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
16. [illegible] general PRACTICE. Present [illegible] ge scope. Advice and medicine [illegible] /- to 15/-. Midwifery refused [illegible] on, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.
17. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200 Premium 1½ years' purchase.
18. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£80, with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented. Prem. 1½ yrs.' pur.
19. WILTSHIRE.—Unopposed old-estab. Country PRACTICE, situated in very pretty district and averaging £700 p.a., including Union appt. £70, and panel producing £450. Nearest opposition 3½ miles Railway station 1 mile. House stands in own grounds of 1½ acres, with tennis court, garage, etc., and contains surgery, 3 reception, 5 or 6 bedrooms, bathroom (h. & c.). Electric light plant installed. Vendor's freehold, price £2,500, all of which could remain on mortgage if wished. Premium £1,050.
20. MANCHESTER.—Rapidly developing outlying suburb. Good middle- and working-class PRACTICE, increasing and producing for the last 12 months over £1,500. Panel of 700. Fees from 3/6. Particularly good house, specially built, and containing 3 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price £3,550, part on mortgage. Premium £2,250.
21. ESSEX COAST.—FAVOURITE RES[illegible] PARTNERSHIP.—A one-third share to commence with in [illegible] Practice. Average income of about [illegible] 4/6 to 21/-. Little midwifery. obtained. Premium 2 years' purchase.
22. BEDFORDSHIRE.—Small Country PRACTICE, at present producing at the rate of £400 p.a., but offering good scope. Fees 3/6 to 10/6, medicine extra. Good house, with 2 reception, 6 bedrooms, etc. Separate entrance to professional rooms. Can be rented on lease. Price for Practice and house £1,050.
23. SOUTH COAST.—FAVOURITE HOLIDAY RESORT.—Well-established non-dispensing PRACTICE. Average income about £1,100, including panel of 1,200. Consultations 2/6 to 10/6, visits 3/6 to 21/-. Practically no midwifery. Very good house, in best position on sea front. Price for leasehold (with 20 years to run at a ground rent of £4 p.a., and renewable) £2,250. Premium £1,800.
24. RIVERSIDE TOWN, within 60 miles of London.—Well-established upper and middle-class PRACTICE, producing about £1,600 p.a., including panel of 200. Surgery fees from 2/6, visits 3/6 to 21/-. Little midwifery. Good house, with large garden. Garage. Rent on lease £100 p.a. Premium £2,200.

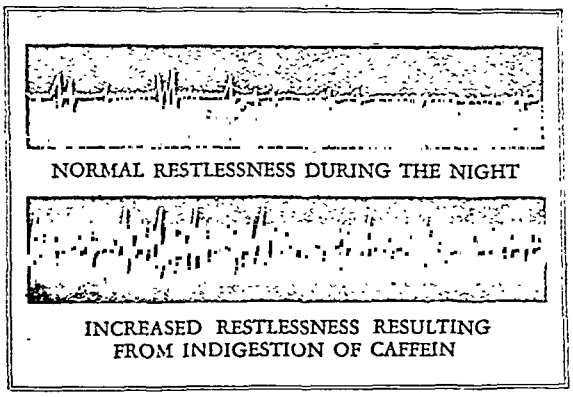
For neural patients

DELICIOUS

H.A.G. COFFEE

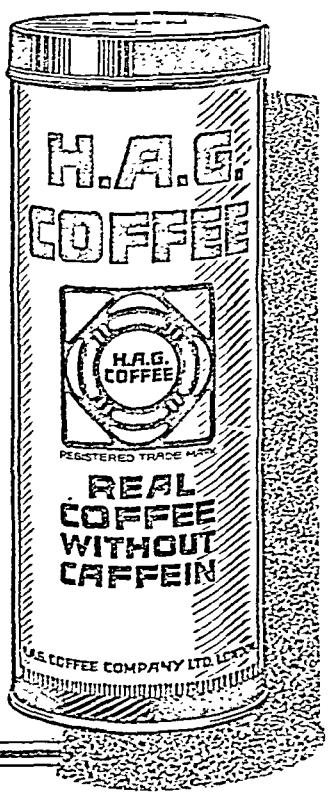
— 97% DECAFFEINIZED



CAFFEIN is never prescribed for neurasthenia, hysterical, insomnious or psychopathic patients. It is too well known how this drug shortens reaction time, excites the reflex arch of the spinal cord, and stimulates the nervous system generally, as shown on the chart at the right.

This is why coffee is forbidden is such cases. But it is not necessary to make this usually vain attempt to change the habits of coffee drinkers. Instead of saying "Stop coffee" simply say "Drink H.A.G. Coffee." H.A.G. Coffee causes practically no increase in nervous stimulation, as the illustration above indicates.

Price per large "Household Size" tin, in the Bean or Ground, 3/2.



NOT A SUBSTITUTE

H.A.G. COFFEE, although 97% decaffeinized, is not a substitute It is blend of the choicest Central American and South American coffee berries, combined in just the right proportion to give that tasty fragrance and flavour found only in coffees of the highest grade Its taste is not impaired in the slightest because the caffein is extracted from the raw beans—before they are roasted.

H.A.G. Coffee is the same coffee as the coffee known on the Continent as "Kaffee HAG" and in America as "SANKA COFFEE." It is very highly recommended by the Medical Profession abroad and practically no other coffee is consumed in such health resorts as Bad Nauheim, Carlsbad, etc., etc.

A free sample, together with an interesting booklet, "Contra Indications of Caffein" by Professor Dr. Mendelsohn, Berlin, is supplied to the Medical Profession upon application.

THE ROAD TO RECOVERY

The Convalescent period calls for all the doctor's tact. Resistance to limitations and restraints grows stronger each day, and the patient's increasing sensitiveness and awareness make it ever more difficult to impose nauseous drugs or distasteful routine.

Apart from the prescription of suitable exercises and foods, perhaps the greatest and most general need during this important stage of illness is the regular and thorough elimination of alimentary waste, with the minimum of discomfort and physiological disturbance. For this purpose, an ideal laxative is Eno's "Fruit Salt." Its superiority is shown by—

1. Its invariable chemical purity.
2. Its unique physical texture.
3. Its ready and uniform solubility.
4. Its freedom from sugar and flavouring agents, as well as from harsh mineral aperients, such as Epsom and Glauber salts.
5. Its entirely local action, produced by the methods of Nature herself.
6. Its agreeable and refreshing natural taste, and its painless action.
7. Its unblemished sixty-year record—ethical and therapeutic.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

See "MEDICAL WORLD," August 24th, 1928:

"An analysis of the cases reported by these writers, in addition to those published by Aufrecht, as well as the cases treated by us, shows a mortality of 20 per cent. in over 2,200 cases of pneumonia in which quinine was not administered, whereas it amounted to only 9.6 per cent. in approximately 1,000 cases in which injections of quinine were given either in the early or late stages of the infection."

A difference between 20 per cent. and 9.6 per cent.!

THE INJECTIONS ARE PAINLESS.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

J. & A. CHURCHILL

NEW BOOKS

85th Annual Issue. 2,200 pages. 54,000 names. 14 Pictures of Spas. 36s. net, postage 1s.

The MEDICAL DIRECTORY, 1929

Including the BRITISH HEALTH RESORTS SECTION, Edited by R. FORTESCUE FOX, M.D.

"This valuable book of reference remains as indispensable as ever."—BRITISH MEDICAL JOURNAL, December 15th, 1928.

NOW READY. 99 Illustrations. 12s. 6d., post. 6d.

SURGERY IN THE TROPICS

By Sir FRANK P. CONNOR, D.S.O., F.R.C.S., D.T.M. & H., Professor of Surgery, Medical College of Bengal, Calcutta, and Surgeon to College Hospital.

NOW READY. 18 Illustrations. 8s. 6d., postage 6d.

CLINICAL CHEMICAL PATHOLOGY

By FRANK SCOTT FOWWEATHER, M.D., M.Sc., D.P.H., F.I.C., Lecturer in Chemical Pathology, University of Leeds. Foreword by Sir BERKELEY MOYNIHAN, Bt., K.C.M.G., C.B., President of the Royal College of Surgeons of England.

NOW READY. With 13 Coloured Plates and 49 Text-figures. 15s., postage 9d.

RADIUM TREATMENT OF CANCER

By STANFORD CADE, F.R.C.S., Assistant Surgeon, Joint Lecturer on Surgery and Teacher of Practical Surgery, Westminster Hospital.

NOW READY. New (4th) Edition. 54 Illustrations. 5s., postage 4d.

ELEMENTARY HYGIENE FOR NURSES

By H. C. R. DARLING, M.D., F.R.C.S.

NOW READY. Third Edition. 10s. 6d., postage 6d.

MALAY POISONS & CHARM CURES

By JOHN D. GIMLETTE, M.R.C.S., L.R.C.P., Late Res. Surg., Kelantan, Unfederated Malay States.

208 Illustrations. 12s. 6d., postage 6d.

THE PRACTICE OF REFRACTION

By W. S. DUKE-ELDER, M.D., F.R.C.S., Assistant Ophthalmic Surgeon, St. George's Hospital.

Remarkable Success. *Two Editions in 18 months.*

NOW READY. New (Second) Edition. 674 Illus. Two Volumes. 28s., postage 1s. 3d.

THE SCIENCE AND PRACTICE OF SURGERY

By W. H. C. ROMANIS, F.R.C.S., and P. H. MITCHINER, F.R.C.S., Teachers of Surgery, St. Thomas's Hosp.

"A well-balanced account of the Science and Art of Surgery as practised at the present day. . . . A student preparing for a pass examination in Surgery need not buy a number of books dealing with its different branches. If he absorbs the information contained within the covers of these volumes he will certainly satisfy the examiners, and will, moreover, have acquired a very good basis of knowledge for higher degrees in Surgery. . . the authors are to be congratulated . . . a very useful and practical manual for the undergraduate student. The price is very moderate."—THE LANCET.

12s. 6d. each except

RECENT ADVANCES

Children & Surgery 15s. each.

BACTERIOLOGY. J. HENRY DIBLE, M.B., Ch.B. 24 Illustrations.

MEDICINE. G. E. BEAUMONT, D.M., F.R.C.P., and E. C. DODDS, M.D., M.R.C.P. Fourth Edition. 48 Illustrations. 4 Editions in 4 years.

OPHTHALMOLOGY. W. STEWART DUKE-ELDER, D.Sc., M.D., F.R.C.S. Second Edition. 4 Coloured Plates and 73 Text-figures.

DISEASES OF CHILDREN. W. J. PEARSON, D.S.O., D.M., F.R.C.P., and W. G. WYLLIE, M.D., M.R.C.P. 18 Plates and 32 Text-figures.

"It should certainly be read by those interested in modern medicine . . . a familiar subject approached on unusual lines."—BRITISH MEDICAL JOURNAL.

BIOCHEMISTRY. JOHN PRYDE, B.Sc., M.Sc. Second Edition. 38 Illustrations.

"This compact work, which covers a wide field in an admirably balanced manner, should certainly be extremely popular."—BRITISH MEDICAL JOURNAL.

HÆMATOLOGY. A. PINEY, M.D. Second Edition. 4 Coloured Plates and 18 Text-figures.

"A thoroughly up-to-date review which original workers cannot fail to find very helpful."—BRITISH MEDICAL JOURNAL.

PSYCHIATRY. H. DEVINE, O.B.E., M.D.

NEUROLOGY. W. RUSSELL BRAIN, M.D., and E. B. STRAUSS, B.M., B.Ch. 38 Illustrations.

SURGERY. W. HENEAGE OGILVIE, M.D., F.R.C.S. 108 Illustrations.

"A clear, concise, and systematic account of the latest work in all branches of surgery."—THE LANCET.

ANATOMY. H. WOOLLARD, M.D. 4 Coloured Plates. 73 Text-figures.

"There is much information in this book. . . . its success is certain."—THE LANCET.

TROPICAL MEDICINE. Sir LEONARD ROGERS, M.D., F.R.S. 12 Illustrations.

"Eminently readable; the historical method adopted adds considerably to its interest . . . under diagnosis and treatment, it is full of important practical points."—BRITISH MEDICAL JOURNAL.

OBSTETRICS AND GYNÆCOLOGY. ALECK W. BOURNE, M.B., B.Ch., F.R.C.S. Second Edition. 67 Illustrations.

"For this second edition we predict as warm a welcome as that accorded to its predecessor."—THE LANCET.

PHYSIOLOGY. C. LOVATT EVANS, D.Sc., F.R.S. Third Edition. 86 Illustrations. 3 Editions in 3 years.

London: 40, Gloucester Place, Portman Square, W.1

The Anglo-French Library of Medical and Biological Science

Edited by F. G. CROOKSHANK, M.D., F.R.C.P., and RENÉ CRUCHET, Professor in the University of Bordeaux, this important series will present the results of recent research in medicine. Books by English, French, and [illegible] will appear in due course.

FIRST TWO VOLUMES.

EPIDEMIOLOGY OLD & NEW

By SIR WILLIAM HAMER, M.A., M.D., F.R.C.P.

9s. net.

"Any book from him is sure of a welcome and of careful consideration. The book is an important contribution to the study of epidemiology, and should be read by all who practise the science and art of medicine."—*Medical Officer.*

ASPECTS OF AGE, LIFE, & DISEASE

By SIR HUMPHRY ROLLESTON, Bt., K.C.B., M.D., D.C.L., LL.D.

10s. 6d. net.

"Thirteen studies, each of which betrays an intimate acquaintance with the general and professional literature, and a capacity to make out of varied details a pleasing, instructive, and inspiring story. The universal attitude towards his volume will certainly be one of gratitude."—*Brit. Med. Journ.*

Other volumes in preparation by Sir St Clair Thomson, Drs. Gibson, Crow, Draper, Professors Achard, Billard, Leriche, and others.

MODERN BIOLOGY

By J. T. CUNNINGHAM. 10s. 6d. net.

"All will admit he has written a book which deserves to be read and studied by medical men as well as professional biologists. In the present work he tests his convictions by passing in critical review all that has fallen in recent years from laboratories where the processes of life are studied by experimental methods."—*British Medical Journal.*

KEGAN PAUL, Broadway House, 68-74, Carter Lane, London, E.C.

THE SYNOPSIS SERIES OF FOUR VOLUMES (value 64s.) for 57s. 6d. net, postage 1s.; or separately as below.

4th Edition. Crown 8vo. 1,000 pp. Fully Revised. 21s. *net, postage* 9d.

SYNOPSIS OF MEDICINE

By H. LETHEBY TIDY, M.A., M.D., B.Ch. (Oxon.), F.R.C.P. (Lond.), Asst. Phys., St. Thomas's Hospital; Cons. Phys., Royal Northern Hospital.

"Far ahead of any medical synopsis it has been our lot to encounter."—*Lancet.*

3rd Edition. Fully Revised. 171 Illustrations. 15s. *net, postage* 6d.

SYNOPSIS OF MIDWIFERY & GYNÆCOLOGY

By ALECK W. BOURNE, B.A., M.B., B.C.(Cantab.), F.R.C.S.(Eng.), Sen. Obst. Surg., Queen Charlotte's Hosp.; Obst. Surg. Out-Patients, St. Mary's Hosp.

"The book is to be recommended both to the student and to the general practitioner."—*Brit. Med. Jour.*

8th Edition. Revised and Enlarged. Crown 8vo. 680 pp. With 164 Diagrams (some in colour). 17s. 6d. *net, postage* 6d.

SYNOPSIS OF SURGERY

By E. W. HEY GROVES, M.S., M.D., B.Sc.(Lond.), F.R.C.S. (Eng.), Surgeon, Bristol General Hospital; Professor of Surgery, University of Bristol.

"Deserves thoroughly all the success it has attained."—*Lancet.*

Crown 8vo. 262 pp. Illustrated. 10s. 6d. *net, postage* 6d.

SYNOPSIS OF PHYSIOLOGY

By A. RENDLE SHORT, M.D., B.S., B.Sc.(Lond.), F.R.C.S.(Eng.), Surgeon, Bristol Royal Infirmary; Lect. on Phys., University of Bristol; and C. I. HAM, M.B., B.Ch., M.R.C.S., L.R.C.P., late Demonstrator in Physiology, University of Bristol.

"Provides in a compact, effectively arranged, lucidly expressed form, an outline of physiology which will be helpful to all students."—*Med. Press and Circ.*

IMPORTANT ANNOUNCEMENTS

READY NEXT WEEK. Size 10" × 7½". Pp. xvi + 376. With 4 Coloured Plates and 220 Illustrations.
Price 30s. Postage: Inland, 9d.; Abroad, 1s.

PROTOZOOLOGY: A Manual for Medical Men

By JOHN GORDON THOMSON, M.A., M.B., Ch.B., Director, Department of Protozoology, London School of Hygiene and Tropical Medicine.
AND
ANDREW ROBERTSON, M.B., Ch.B., Lecturer and Milner Research Fellow in the Department of Protozoology, London School of Hygiene and Tropical Medicine.

¶ *This work gives a clear account of the morphology and mode of life of the protozoal parasites which are important as the cause of disease in man, and, at the same time, to describe their life-histories, on a knowledge of which can be based intelligent preventive measures.*

NOW READY. Size 9½" × 6½". Pp. xii + 304. With 200 Illustrations. Price 30s. Postage: Inland, 9d.; Abroad, 1s.

HELMINTHOLOGY: MEDICAL AND VETERINARY

By H. A. BAYLIS, M.A., D.Sc., Assistant Keeper, Department of Zoology, British Museum (Natural History).

¶ *This work brings together under one cover a full account of the numerous species of worms parasitic in man and the domestic animals. The available descriptions of many of these have, until now, been scattered through a vast mass of periodical literature which has not been readily accessible.*

JUST PUBLISHED. Size 10" × 7". Pp. xii + 354. With 751 Illustrations. Price 42s. Postage: Inland, 9d.; Abroad, 1s. 6d.

KÖHLER'S RÖNTGENOLOGY

The Borderlands of the Normal and Early Pathological in the Skiagram.

Rendered into English from the FIFTH GERMAN EDITION by ARTHUR TURNBULL, M.A., B.Sc., M.B., Ch.B.(Glasg.).

¶ *"There can be no doubt that this book is a radiological classic. . . . There is no book on radiological diagnosis written on the same lines as Köhler's. . . . It is indispensable to all radiologists and orthopædic surgeons, and many others should find it of great use."*—BRITISH MEDICAL JOURNAL.
"The book is quite invaluable for purposes of reference."—BRITISH JOURNAL OF SURGERY.

A practical Dictionary, including Dental, Veterinary, Chemical, Botanical, and other special terms.

NOW READY. TENTH EDITION, Revised, with the introduction of several hundred new titles.

STEDMAN'S MEDICAL DICTIONARY

¶ *"A special feature of this dictionary, which adds greatly to its usefulness, is that diseases, operations, and the like, are described under the proper names, so that no time is lost, as is the case with some other dictionaries, in which one is referred from the proper names to a description elsewhere."*—BRITISH MEDICAL JOURNAL.

Size 9½" × 6½". Pp. xii + 1,194, double columns, with 15 Plates and over 400 Illustrations, of which 64 are coloured.
Limp leather, with thumb-cut index. Price 35s. Postage: Inland, 1s.

"A well-written, sound book of a reasonable length."—ST. BARTHOLOMEW'S HOSPITAL JOURNAL.

READY NEXT WEEK. SECOND EDITION. Thoroughly Revised and Enlarged. Price 12s. 6d.

BIGGER'S HANDBOOK OF BACTERIOLOGY

"A book which gives all a medical student is likely to be asked about bacteriology."—BRITISH MEDICAL JOURNAL.
"It satisfies what was undoubtedly a real want."—LONDON HOSPITAL GAZETTE.

NOW READY. SECOND EDITION. Pp. x + 231, with 9 Plates and 30 Illustrations. Price 12s. 6d. Postage 8d.

PHYSIOTHERAPY IN GENERAL PRACTICE

By E. BELLIS CLAYTON, M.B., B.Ch.(Cantab.).
Director of the Physiotherapeutic Department at and in charge of the Massage and Electrical School, King's College Hospital, London.

"A book which should prove of great value to the general practitioner."—GLASGOW MEDICAL JOURNAL.

NOW READY. Minor Monograph Series. Price 5s. Postage 4d.

VARICOSE VEINS

and Their Treatment by "Empty Vein" Injection.

By RONALD THORNHILL, M.B., Ch.B.
With Foreword by Sir BERKELEY MOYNIHAN, Bart., K.C.M.G.

Seventh Edition. WHITLA'S Price 25s.

DICTIONARY of TREATMENT

Includes details of the treatment of Medical, Surgical, Gynæcological, Obstetric, Cutaneous, Eye and Ear Diseases.

7 & 8, Henrietta Street, Covent Garden, London, W.C.2.

ROLLS-ROYCE

The Best Car in the World

"More than ever it is a delight. What a truly amazing composition is this apotheosis of the Automobile." — Reprinted from *Car and Golf, July 1928*

ROLLS-ROYCE LIMITED

14-15 Conduit Street, London, W.1

Equip Your CHAUFFEUR at GAMAGES

Thousands of Britain's smartest Chauffeurs wear Gamages' Liveries. It is because wise employers know that at Gamages they not only obtain finest quality cloths and perfect tailoring, but that they pay prices which are most economical. Here are two typical examples of the astounding values Gamages offer.

The GAMAGE "BROOKLANDS"

Perfectly fitted to every need of the Chauffeur. This fine suit comprises Double-breasted Jacket and Trousers made from good weight indigo dye All-Wool Blue Serge. Fittings for all sizes from stock. £5/15/6, 95/-

84/-

The GAMAGE "CAVENDISH"

Made from hard-wearing Blue Melton cloths and lined Tweed throughout. Overcoats are made in two styles—(1) as illustrated; (2) button to neck. Ready for service in all fittings. 115/6; 95/-; 84/-.

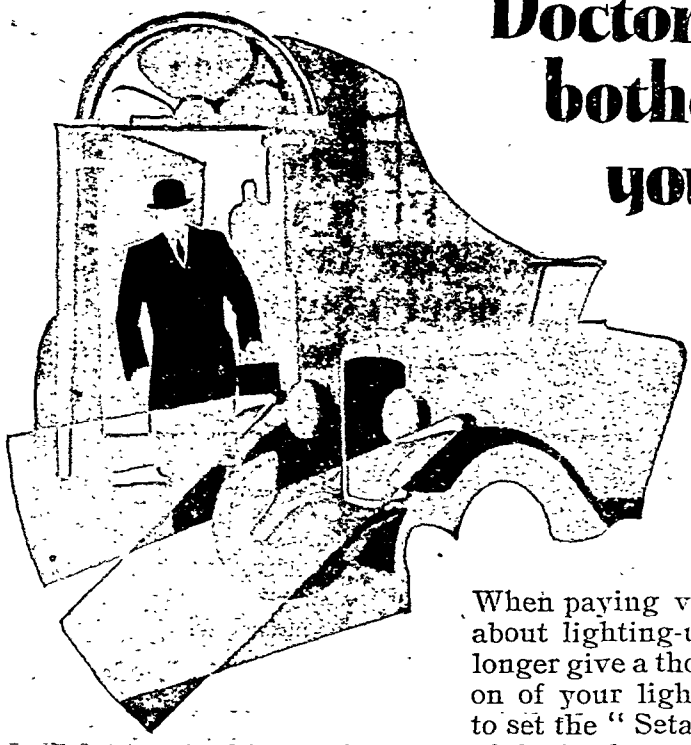
70/-

GAMAGES

A. W. GAMAGE Ltd., HOLBORN, LONDON, E.C.1

City Branch: 107, CHEAPSIDE, E.C.

ARE YOUR LAMPS POLICE-PROOF?



Doctors...don't bother about your car-lights

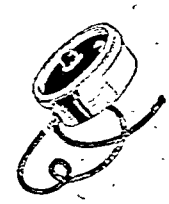
When paying visits to patients, just about lighting-up time, you need no longer give a thought to the switching on of your lights. For you've only to set the "Setalite"—just one twist of the knob—and the lights come on automatically and unfailingly at the right moment.

ORDERS FROM DOCTORS RECEIVE PRIORITY.

The "Setalite" is also indispensable for evening visits to friends' houses, bridge parties, theatres and when shopping, etc. It is a neat little fitment (rather like a speedometer) which you can fix yourself, anywhere on your car, in a minute or two. It is weather-proof and practically unbreakable. It requires no winding and uses no current whatever. It is a universal voltage instrument, and does not in any way interfere with your present lighting system or prevent your switching on by the ordinary switch. It will greatly increase the life of your battery.

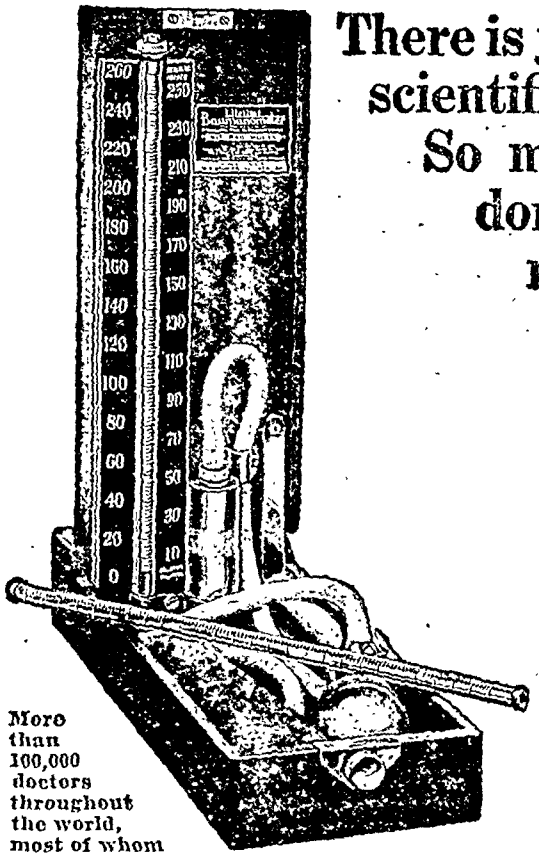
Price 45/-, or on deferred payments. If unobtainable from your dealer, write direct to:
SETALITE LTD., 316, REGENT STREET, W.1.

SETALITE



"The only thing of its kind in the world."

THE LIGHTS LIGHT THEMSELVES AT LIGHTING-UP TIME



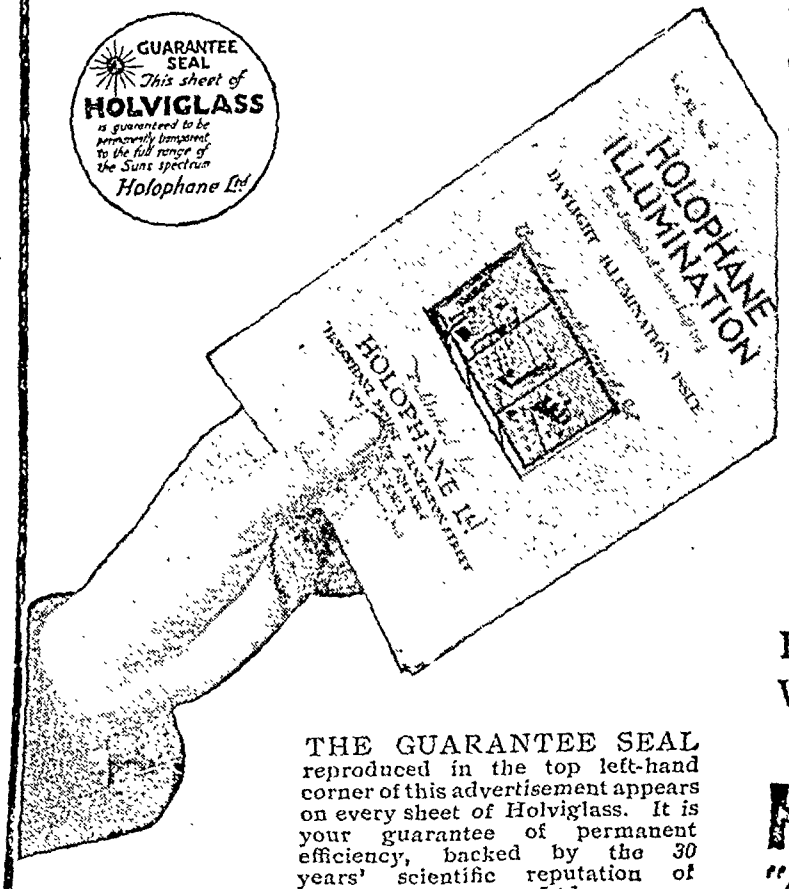
More than 100,000 doctors throughout the world, most of whom previously used *aneroid*, spring, or air compression manometers now use the Baumanometer.

There is just so much real worth built into any scientific instrument—So much accuracy—So much reliability—So much freedom from expensive upkeep—So much service—So much satisfaction—The most ever built into a blood-pressure instrument is built into the NEW

Lifetime Baumanometer
"STANDARD FOR BLOODPRESSURE"

OBTAINABLE FROM ALL DEALERS, OR FROM THE BRITISH DISTRIBUTORS:

HAWKSLEY & SONS, Ltd., 83, Wigmore St., London, W. 1



THE GUARANTEE SEAL reproduced in the top left-hand corner of this advertisement appears on every sheet of Holviglass. It is your guarantee of permanent efficiency, backed by the 30 years' scientific reputation of Holophane Ltd.

THE TRUTH ABOUT ULTRA-VIOLET RAY GLASS

is fully explained in the "Daylight Illumination" issue of *Holophane Illumination*, a free copy of which is offered to every reader of this paper.

In this issue the whole subject is fully discussed and a detailed description given of HOLVIGLASS, the new and improved ultra-violet ray glass which is sold under a *definite guarantee of permanence.*

Write for your copy *to-day* (sent free and post free).

HOLOPHANE LTD., 63 ELVERTON ST. VINCENT SQUARE, LONDON, S.W.1

Influenza and Capillary Tone

Another influenza epidemic finds us still without a specific preventive or a specific remedy. Fortunately, both the incidence and the course of the disease can be favourably modified by the observance of such rules as medical experience teaches.

It is essential to maintain vigorous metabolism and healthy capillary tone, whilst avoiding undue cold and damp. Adequate stimulation of the sensory nerve-fibrils of the skin, also, is of supreme importance in keeping the body's resisting power at its highest, and in increasing its recovery-capacity. For these purposes, THERMOGENE has been found by many medical men and their patients to be convenient, cleanly and effective.

Thermogene is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

THERMOGENE
MEDICATED WADDING

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with Thermogene and its many uses in practice.
The Thermogene Co., Ltd., Queen's Road, Hayward's Heath, Sussex.

INFLUENZA

The experience of physicians who have used Mulford Influenza Serobacterin Mixed, in industrial institutions and private practice, has confirmed their belief in its efficiency, both as a prophylactic and therapeutic agent.

The structural formula of Mulford Influenza Serobacterin Mixed has been maintained unchanged since its introduction in 1910, but in the meantime, particularly during the influenza epidemic of 1918, new strains of bacteria have been added, thus increasing its polyvalency and efficiency. These bacteria include:

Influenza Bacillus (Pfeiffer)	Pneumococcus (Types I, II, III, IV)
Streptococcus (hemolytic and viridans)	Micrococcus catarrhalis
Staphylococcus (aureus and albus)	Bacillus Friedlander

As immunity is only relative, there is an advantage in four injections, beginning with a small initial dose, progressively increased, thus affording a more complete and lasting immunity.

Influenza Serobacterin Mixed is supplied as follows:
- M 109-0—4-syringe ... 1 immunization
- M 109-9—5 c.c. ... 2 immunizations
- M 109-4—20 c.c. ... 8 immunizations

Intestinal Disinfection

FLATULENCE AND ALIMENTARY FETOR

MANY conditions are associated with flatulence, some of which frequently give rise to embarrassment of distant organs.

Dyspepsia, catarrh and ulceration of the stomach and intestine, cancer, dysentery, and other diseases of the alimentary canal itself, neurasthenia, and diseases of the heart, liver and pancreas, to name only a few, may all be associated with flatulence and intestinal flatus.

Some of the diseases of the intestine, such as dysentery and cancer, are often also associated with horrible fetor of the evacuations.

The accumulation of flatus in the stomach and intestine is liable to embarrass the action of the heart and lungs, giving rise to dyspnœa, disordered action of the heart, faintness and even anginal attacks.

Both the flatulence and fetor are the result of abnormal fermentation and putrefaction of the contents of the alimentary canal; apart from treatment of the condition itself, it can be rationally controlled by the use of an efficient intestinal disinfectant. For this purpose, Kerol, the most potent germicide, being unabsorbed and non-toxic, is unsurpassed, and can be safely administered in sufficient amount to exert its germicidal action.

When the fermentation is located in the stomach, KEROL CAPSULES (Gastric) m. 3, should be administered: one or two may be given three or four times a day after meals.

When there is intestinal flatus and fetor, the keratin-coated KEROL CAPSULES m. 3, should be used, the dose being one to three after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

K7

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor is cumulative in action, and, in ordinary cases of insomnia, one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used when the heart is weak. Where sleeplessness is a concomitant of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETO-SALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN. Price 10/6 per lb. In 5, 10, 22, 40, and 90 oz. Bottles.

Introduced and Prepared only by

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

For Ill Conditions of the Gastric Tract

"Alocol" is the practitioner's safeguard when alkaline medication is indicated. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia, and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed, which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

The advantages of "Alocol" are therefore manifest. It neither hinders proteolysis nor causes destruction of any food element or factor. Prolonged exhibition interferes in no way with the normal putrefactive function of the gastric juices, or with the regular processes of nutrition.

"Alocol" is regarded as a specific in the treatment of hyperchlorhydria, whilst for all forms of fermentative dyspepsias, with gastro-intestinal flatulence, acid eructations, and other symptoms common to gastric disease, its influence is beneficial to the highest degree.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

The Value of Lysolats for Hospital Use

It is regrettable that, in the choice of antiseptics in hospitals for the operating theatre and general use, Dispensers are apt to value a substance from the chemical rather than from the bacteriological point of view.

Lysolats and all saponified tarry preparations are generally considered on their cresylic acid content, which, although an important figure, is not a criterion of efficiency.

Lysolats are a standard preparation assayed by the Rideal-Walker and Martin-Chick tests. Other bacteriological experiments carried out by Professor Huynen in the laboratories of the State Veterinary University of Brussels show that a 1% solution of Lysolats in water stops the developments of bacterial growth in two seconds.

A 1% solution of Lysolats was tried on the following organisms:—

B. Coli	was killed in	40	seconds.
B. Bang	,,	,,	,,
B. Pneumococci	,,	,,	,,
B. Typhosus	,,	,,	,,
B. Staphylococci	,,	50	,,
B. Pyocyaneus	,,	,,	,,

The attention of Surgeons, House Doctors, and all engaged in hospital work is drawn to this preparation, which is the most efficient and safe antiseptic produced by Chemical Science.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney Street, London, S.E.1.

Lysolats

PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Prescribe 'Mistol' for the Nose and Throat.

MISTOL has proven especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Mistol consists of menthol, eucalyptol, and camphor carefully combined in proportions recommended by leading nose and throat specialists. A specially prepared petroleum base keeps the soothing, healing ingredients in direct contact with the mucous membrane for a considerable length of time. Moreover, it prevents it being easily washed away by the natural secretions.

Mistol and the Mistol Dropper are a real advance in nose and throat therapy. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. Unlike douches, Mistol avoids any possibility of sinus trouble. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Sold in original sealed cartons containing a—

The Influenza Prophylactic

The importance of taking early measures for the prevention of influenza need not be over-emphasised. In a recent number of this journal (January 12th, page 73) attention was directed to the prevalence of influenza abroad and to the likelihood of an epidemic spreading in this country.

Vitamin A has been shown to possess specific anti-infective action, particularly in inflammatory conditions of the respiratory tract. An increased daily intake of Vitamin A is clearly indicated at this period. Radio-Malt contains Vitamin A in accurately-calculated quantities standardised in the B.D.H. laboratories by recognised chemical and physiological tests.

Physicians prescribing Radio-Malt, whether for their influenza patients or as a prophylactic for whole families, know that ample supplies of Vitamin A are provided. For this reason Radio-Malt is proving to be so valuable in the campaign against influenza.

WRIGHT'S LYSOL

BRITISH MADE :: :: BRITISH OWNED

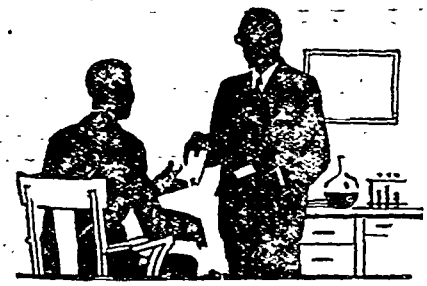
The quality of WRIGHT'S LYSOL has never been questioned

It is safe to prescribe Wright's Lysol — safe because you know that your patients will then get a pure and highly refined Lysol, controlled by the Rideal-Walker test. Wright's contains no free alkali — does not sting or irritate — gives certain results. It is widely used by the profession; Hospitals and Nursing Homes prefer it. Tell your patients always to say "Wright's" before "Lysol."

British owned and British made by the makers of the world famed Wright's Coal Tar Soap.

A handy graduated measure is provided with every bottle.

Streets 51



Coated Tongue and Toxemia

Coating on the tongue consists of epithelial cells, molds, yeast, and many bacteria, some highly virulent. Normally the saliva prevents growth of the latter. If the resistance of the blood is lowered, the saliva loses its germ-destroying and inhibiting power. A tongue coating appears.

In the constipated colon, putrefactive bacteria produce highly active poisons such as skatol, indol, etc. These enter the blood, lower its resistance, and thus weaken all fluid secretions such as the saliva. No wonder 85 per cent. of all sick people have coated tongues. Constipation is almost universal among the sick.

If the tongue indicates toxemia, prescribe Nujol—the safe and effective treatment. Many intestinal toxins are themselves absorbed by Nujol.

Nujol

REGISTERED TRADE MARK

Once absorbed by Nujol, intestinal toxins cannot be absorbed by the system, as Nujol itself is non-absorbable.

The Source of NOURISHMENT

VITAMIN B

Outstanding advantages of HOVIS

Of all kinds of bread consumed to-day, HOVIS is richest in Vitamin B, which encourages growth and increase of weight. Bulk for bulk it supplies a greater amount of nourishment.

HOVIS combines all the benefits of white flour with 25 per cent. of the wheat germ, the part richest in the vitamin, added.

Compared with other cereals, the Vitamin B content of milling products and yeast in 100 g. dried bread is as follows:

White Bread	200
Wholemeal Bread ...	1,450
HOVIS Bread	2,600

The great value of HOVIS is that it contains all the elements of a complete food; it is universally liked, and containing no bran is easily absorbed.

It is also most economical, the quantity necessary to furnish sufficient nourishment being very small.

Were HOVIS to form a part of everybody's daily diet the nation would undoubtedly be better nourished.

"OF IMMENSE PSYCHOLOGICAL IMPORTANCE"

"I have prescribed Bemax for a considerable time in my practice and I have found it the most valuable food at present on the market. Apart from its nutritive value the general experience of patients is that since taking it they never require aperient medicine. This, as you will readily understand, is in itself a most valuable factor, as it enables those patients to secure a natural daily evacuation, which is of immense psychological importance." M.D.

Bemax is now established as the B vitamin food. Over 25,000 members of the medical profession are taking Bemax themselves or prescribing it for their patients, with excellent results. The diseases for which medical men are prescribing Bemax are Constipation, Intestinal Toxaemia, Debility, Neurasthenia, Rheumatism, Gastric disturbances and all forms of skin disease. In fact, any ailment due to B vitamin deficiency. If you have not tried Bemax, a free full size tin will be sent you on receipt of your professional card.

On the Absorption of Sanatogen

Why it is that Sanatogen is absorbed with ease even by the weakest stomach.

The tonic influence of the glycero-phosphoric-acid in the chemical combination casein-sodium glycerophosphate (Sanatogen) makes the use of casein possible in cases where the patient has to a great extent lost his capacity of absorption (Tunnicliffe, Tischer-Beddies, Chajes, a.o.).

French authorities (Robin and others) ascribe to the glycero-phosphates a great influence on the utilization of the albumin in the body. The manufacture of Sanatogen is conducted under the strictest scientific control ensuring absolute purity, sterility and uniformly high dietetic value.

Samples and Literature will gladly be sent on request to:

GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE.

BOOTS PRODUCTS

Vitamalt (BOOTS)

Rich in essential Vitamins A, B, C, & D

VITAMALT is a scientific preparation containing the finest Malt Extract of high diastatic value, with selected ingredients rich in Vitamins. It is a well-balanced food that ensures an adequate supply of Vitamins A, B, C, and D, and corrects all ailments arising from deficiency of these vital factors. There are many people who are unable to take Cod Liver Oil on account of its oily nature and fishy taste. To such, Vitamalt will prove a boon in supplying the Vitamins A and D, upon which the value of Cod Liver Oil depends.

INSULIN "A.B."

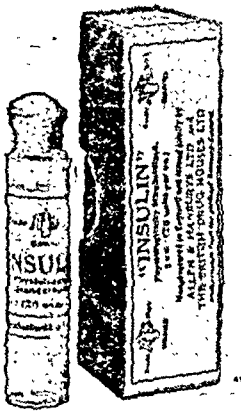
TRADE A B MARKS Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Packed in bottles containing:

5 c.c. (100 units or 10 doses) 2/8 each

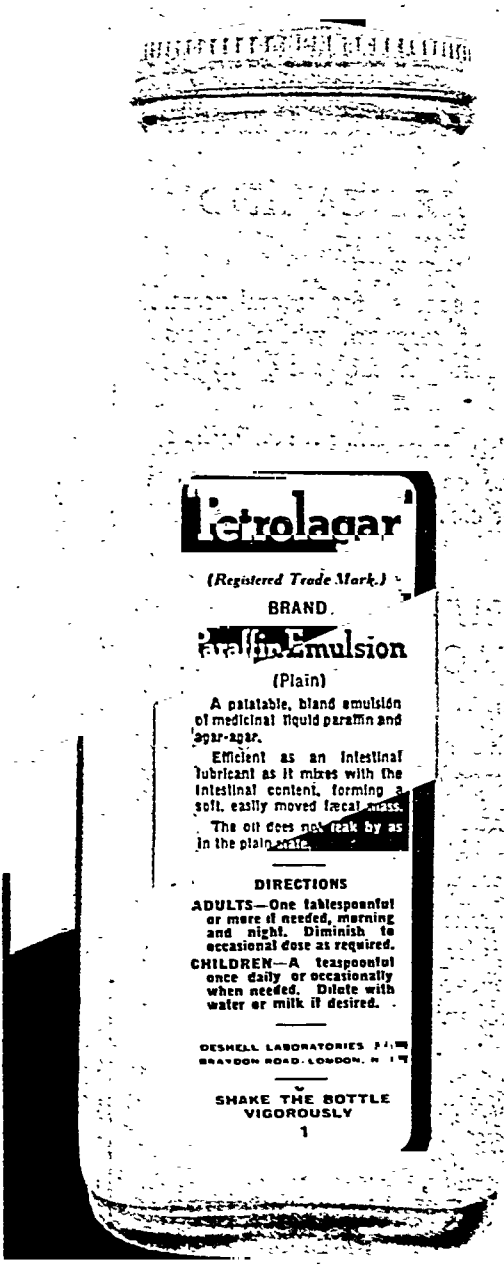
THIS IS NEW



NEW BOTTLE FOR "PETROLAGAR"

We are pleased to announce that in future the 8 and 16 oz. bottles of "Petrolagar" Emulsion will have a wide opening capable of admitting a large spoon.

This improvement has been made because so many Doctors suggested it would be more convenient for their patients.

Write for literature and specimens of the new bottle to:

Deshell Laboratories Ltd.,
Braydon Rd., N.16.

Prescribe "Petrolagar" Emulsion for ten of your patients and note how much more effective it is in every respect than cathartics or plain paraffin.

Alternative Methods in

PROPHYLAXIS & TREATMENT

OF

INFLUENZA & CORYZA

DETOXICATED ANTI-INFLUENZA AND ANTI-CORYZA VACCINES

These Vaccines have been used with great success for several years. Their outstanding feature is the absence of reaction, which makes them especially useful in actual treatment and in the case of hypersensitive patients.

The composition of these Vaccines is highly compound; in addition to other organisms the Influenza Vaccine contains 15,000 millions and the Coryza Vaccine 5,000 millions, per c.c., of the *new Streptococcus isolated from the blood of influenza cases.*

ORDINARY ANTI-INFLUENZA AND ANTI-CORYZA VACCINES

Some Practitioners consider that a slight reaction has definite therapeutic value, and these Vaccines have been prepared to meet their requirements. They have the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY

(For local application to the nose and throat)

For patients who object to Vaccine treatment by subcutaneous injections, and for children, this Local Immunity Product is particularly indicated. It contains the Influenza Streptococci in addition to the various Coryza organisms, and is, therefore, valuable as a prophylactic against Influenza Colds.

¶ *Practitioners desiring further information regarding these Products are invited to write to:*

The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

(*Aesculapius*)

MUSCULAR ATONY

It is well known that hypodermic injections of an extract of the posterior lobe of the pituitary gland exercise a prompt and well sustained effect on non-striated muscle. The application of this knowledge makes available a most valuable agent for the treatment of atonic conditions. Post-pituitary extracts have been usefully employed in intestinal paresis, for the control of hæmorrhage, as a general tonic, and also exert specific effects on the musculature of the cardio-vascular system, increasing tone and thereby raising arterial tension. It is a valuable adjunct in dealing with syncope, extreme exhaustion, and shock. Excellent results are obtained with it in the treatment of pneumonia.

INFUNDIBULIN

This is an extract of the Posterior Lobe of the Pituitary Gland prepared at Evans' Biological Institute. It is standardised so that 1 c.c. contains 10 International Units. In addition to the uses described above, its value in the practice of midwifery is indisputable.

It is available in 1 c.c. and 0.5 c.c. ampoules. Samples on application to

Evans' Biological Institute, Runcorn.

FOR TOXÆMIAS OF INTESTINAL ORIGIN

Kaylene-ol

is an effective detoxicating agent and one of the simplest to employ. It does not merely lubricate the bowel, but also fixes the toxins in the Stool.

It actively prevents the absorption of toxins and completely puts an end to the fouling of the lymphatics and the blood.

KAYLENE-OL C PHENOLPHTHALEIN

CONSTIPATION OF PREGNANCY.

"The preparations of KAYLENE, and especially KAYLENE-OL C Phenolphthalein; are proving useful in pregnancy. The latter gives generally two very easy actions a day, has a helpful effect on the nausea, and lessens the chances of intestinal toxæmias of pregnancy. Further, it need not be taken in increasing doses, but may rather be employed in gradually reduced quantities. As constipation is almost universal in pregnancy, the benefit from such preparations will be apparent."

Samples and particulars of Kaylene and its preparations forwarded on request.

PIONEERS AND EMPIRE BUILDERS: No. 500
EIGHTH PERIOD—circa 750 B.C. to A.D. c. 404

Pernicious Anæmia

TRADE MARK 'WELLCOME' BRAND

LIVER EXTRACT

(An Active Selected Fraction of an Extract of Fresh Liver)

After being subjected to the necessary clinical trials, 'WELLCOME' LIVER EXTRACT was placed at the disposal of physicians.

'WELLCOME' LIVER EXTRACT is prepared by a process tested and found efficient by the Medical Research Council. *(See B.M.J. and Lancet, March 10, 1928)*

Tubes, each containing an active selected fraction of an extract derived from half-a-pound of fresh liver.

DIRECTION.—The contents of one tube, or more, daily, in soup or water, or as directed by the physician.

Supplied at 3/- per tube, and in boxes of 12 tubes, at 36/- per box

Literature free on request

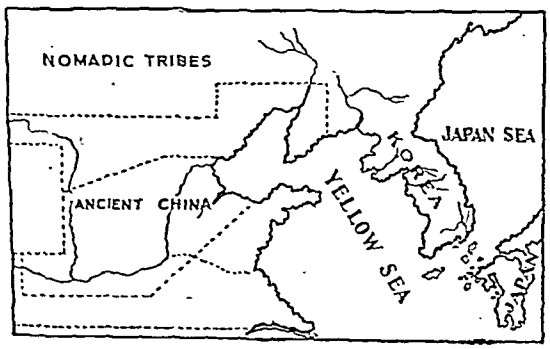
MAP SHOWING THE RELATION OF SIXTH CENTURY B.C. JAPAN TO KOREA AND CHINA THROUGH WHICH CAME THE NORTHERN ASIAN PIONEERS, WHOSE DESCENDANTS CONSTITUTE THE CHIEF ELEMENT AMONG THOSE WHO BUILT UP THE PRESENT EMPIRE OF JAPAN.—According to Japanese legend the great Yomato people worked their way through China and Korea to the Southern extremity of Japan in a succession of migrations lasting several centuries. During the early period their domain hardly passed the narrow limits of the region to which they gave the name Yomato. They waged incessant war against the aborigines, pressing them gradually towards the north and east. Archæology appears to support legend, for the tombs of their great leaders are practically confined to this region The invasions have been attributed roughly to the period c. 1000-500 B.C. Ethnologists agree for the most part that the Yomato came from the regions north of China and that they were partly Caucasic, perhaps Iranian, in origin, with some admixture of Mongolian blood. In course of time the whole country became known as Yomato. This word was changed in A.D. 670 to Nihon or Nippon, the "place of Sunrise." In Chinese this was Jih-pen, which in its turn became, about the fifteenth century, the "Japan" of the West.



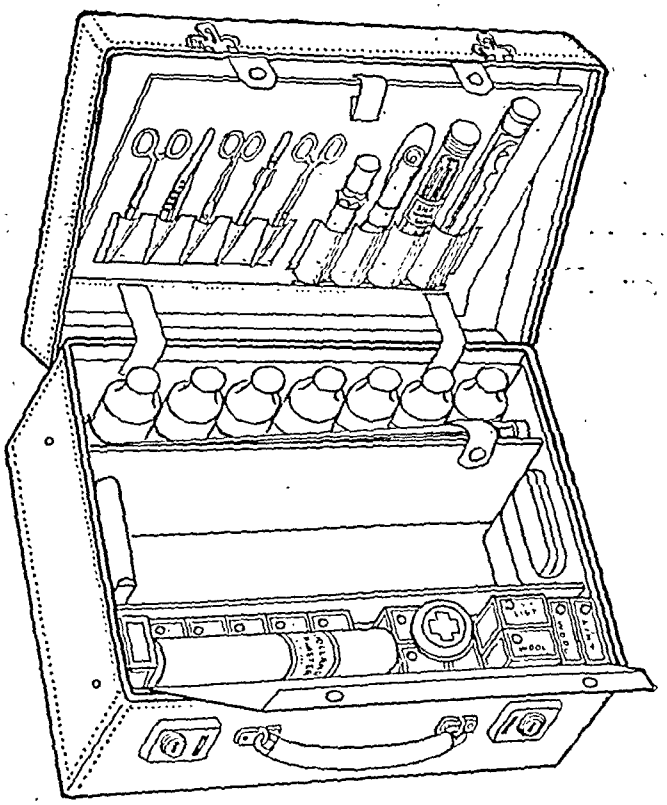
DATE: Yomato immigrations probably c. 1000-500 B.C.

COPYRIGHT

THE

PARATUM

PRACTITIONER'S FITTED BAG.



AS the name implies, this is an equipment at all times in readiness. It can be carried in the car, and there, or in the house, is complete for an emergency call, thus obviating trouble and delay. It contains only those articles which a doctor is likely to require at any time—the central space is left vacant to suit individual requirements.

The bag is of the best leather on a strengthened frame and as light as is consistent with lasting qualities; with contents it weighs 13 lbs.

Dimensions 16 in. by 11 in. by 5½ in.

The arrangement of the contents is as follows:

LID.
2 Artery Forceps.
1 Dissecting Forceps.
1 pair Scissors.
2 Stainless Knives in Sterilizable Glass Tube.
1 Combined Electric Throat Lamp and Tongue Depressor.
1 Hypodermic Syringe in Spirit-tight Case.
1 Half Min. Magnifying Clinical.
1 Tube Silkworm *Gut Medium.*

REAR COMPARTMENT. Seven stoppered bottles in nickel screw-capped cases, each with contents engraved outside as follows:

CHLOROFORM	LYSOL	SOL. ACID PICRIC 5%	SUTURE AND HYPODERMIC
TINCT. IODI	METH. SPIRIT	TABS. HYDRARG. PERCHLOR.	NEEDLES IN ALCOHOL

In front lies a thick glass tube with rubber cork containing No. 8 Gum Elastic Catheter and a tube of Lubricant.

CENTRAL COMPARTMENT. On one side a prescription note-book with pencil and on the other an electro-plated case with clips for tubes of hypodermic tablets. Included also in this compartment is the new Reid-Morris Stethoscope.

FRONT COMPARTMENT. For sundries and dressings with lid to keep the contents in place.

2 oz. Compressed Boric Lint.
2 oz. ,, Plain ,,
6 yds. ,, ,, Gauze.
4 oz. ,, Cotton Wool.
2 Compressed Bandages 3 inch.
3 ,, ,, 2 inch
4 ,, ,, 1 inch.
1 Sterile Throat Swab in Parcel Post Box.
3 Yards Adhesive Plaster 8 inch wide (in roll).
6 Rubber Finger Stalls.
6x 1 c.c. Ampoules Pituitary Principle.

The whole case is lined with glazed, white waterproof material, easily cleaned with a wet sponge.

Price: EIGHT GUINEAS NETT.

A British Medical Association Lecture

ON THE

UNDERLYING DISTURBANCES OF METABOLISM OF THE NERVOUS CHILD.

DELIVERED BEFORE THE WEST SUFFOLK DIVISION

BY

HECTOR CHARLES CAMERON, M.D., F.R.C.P.,

PHYSICIAN IN CHARGE OF THE DEPARTMENT FOR DISEASES OF CHILDREN, GUY'S HOSPITAL.

THE metabolic processes of all children, just because they are children, are less stable than they become in later life. It is in this instability that we find the explanation of the greater frequency in childhood of many disorders due to biochemical derangement—as, for example, eczema, tetany, convulsions, urticaria, or asthma. The peculiar liability of the nervous child to these derangements of metabolism, especially to that common condition known as acidosis, is not only a direct result of his undue sensitiveness to emotional excitement or to physical fatigue, but the state of disordered metabolism so produced is of itself provocative of that restlessness, irritability, or nervousness for which our advice is sought. The nervous child is prone to acidosis, but whenever the symptoms of acidosis are recognizable there is apt to be a simultaneous exacerbation of all the symptoms of nervousness.

The Liability of the Nervous Child to Cyclical Disturbances.

We may look on the nervous child from one point of view as a problem in management, quick to respond to all influences for good, but quick also to react violently even to small mistakes in our management of him. Or, again, we may lay stress upon the physical defects which are so often characteristic of him—the faulty posture, the lax and toneless muscles, the drooping, sagging stance, and the neuro-muscular inco-ordination—all of which are the outward and visible signs of the tired, restless, and irritable brain. But from another point of view we must attempt to probe even more deeply into the problem. We must seek to determine the nature of these recurring waves of disturbed metabolism, which account for the peculiar instability both of physical health and of conduct characteristic of the nervous child, and which are manifested in the "bouts" or "attacks" or "turns" of which, in one form or another, complaint is almost always made. The symptoms which together make up the well-recognized and familiar attack are not the same in different children—in one vomiting, in another nervous diarrhoea; in one drowsiness and prostration, in another restlessness and irritability.

What is the underlying cause of this recurring state of collapse, physical and mental, so characteristic of the nervous child? Why does he so often suddenly fall from a state of comparative well-being to a deplorable condition of weakness, accompanied by loss of weight and loss of colour—with circumoral pallor and dark-rimmed eyes; loss of muscular tone and loss of co-ordination—so that at the worst his walk deteriorates to a mere shuffle and the frequency of his falls becomes a common complaint; loss of energy, so that he lags behind on his daily walks abroad, or, at their conclusion, throws himself down with many significant yawnings and sighings; loss of control, so that clamour, opposition, and tears may become unceasing; and loss of concentration, so that his work at school sensibly deteriorates? And with all these distressing backslidings there are often, almost usually, other complaints—rapid, excitable overaction of the heart, which sometimes leads to a diagnosis of dilatation of the heart; a continuous irregularity of the temperature which cannot but rouse fears of latent tuberculosis; transitory aches and pains in the lax and toneless muscles of the limbs after any exertion, apt to cause confusion with the subacute arthritis of rheumatic fever; and recurrent bouts of abdominal pain of short duration and always accompanied by a striking vasomotor pallor, which must arouse the fear of the presence of appendicitis. The tongue is almost always white, the breath, especially in the early morning, is apt to be charged with the faint odour of acetone, while sleep, always disturbed and restless, is often broken by night terrors or sleep-walking. It may be that vomiting is by far the most prominent feature of the attack, as in the classical picture of so-called cyclical vomiting. More often vomiting is only occasional, or it may be altogether absent. Sometimes nausea and dizziness may be complained of, especially in the early morning; sometimes there may be no complaints of gastric symptoms at all. Lastly, it is when the child falls into this state of pallor and prostration that all nervous symptoms tend to undergo an exacerbation. It will often be found that, coincidently with the state described above, the particular disturbance to which any child is prone—masturbation, enuresis, tics and habitual movements of all sorts, squintings, stammerings, and the rest—spring to life again, and proceed with renewed force.

Glycopenia.

Our food is the source of the energy expended in all the activities of life, physical and mental. Our food contains fat, carbohydrate, and protein in suitable proportions. In general it may be said that comparatively little of the protein is utilized as fuel. The protein is too valuable to be employed merely to provide energy for the machine, and is used mainly for structural repair and replacement. The carbohydrate may be said to be the petrol of choice, that on which our machine is run in the first instance. But we have only a meagre store of carbohydrate in our bodies. In an adult male perhaps about 8 ounces may be stored away in the form of glycogen in the liver and in the muscles. These slender reserves of carbohydrate are readily exhausted, especially by physical exertion, by emotional excitement, and by pyrexia. When so exhausted we may, perhaps, speak of a state of glycopenia. The actual percentage of sugar in the blood varies within well-defined limits. After a meal of starch or sugar the blood sugar rises rapidly to 0.18 per cent., to fall within a few hours to the fasting level of 0.07 per cent. We speak, therefore, of a blood sugar curve. Without the frequent administration of carbohydrate the blood sugar remains constantly at the fasting level. Certain diseased states are characterized by a definite hypoglycaemia, a definitely low blood sugar. In Addison's disease, for example, in which the suprarenal glands are destroyed by caseation, there is often hypoglycaemia accompanied by great vasomotor weakness and pallor, a low blood pressure, a rapid pulse, extreme amyotonia and muscular weakness, prostration and loss of energy, and attacks of nausea and vomiting.

We know that the suprarenal glands are exhausted and that their function becomes impaired under the stress of great exertion, of great emotional excitement, or of persistent infection. These are the same conditions which lead to the exhaustion of the carbohydrate reserves and the fall of the blood sugar to the lowest level, and they are the same conditions which in practice we are forced to regard as productive of the "bouts" or "attacks" of pallor, prostration, and vomiting of the nervous child. If speculation is permitted where certainty is not yet, we may surmise that in Addison's disease we are observing the effects of the gross destruction of the suprarenal tissue; in an attack of cyclical vomiting we are encountering the temporary exhaustion and functional impairment of the same gland. The failure to mobilize by means of the suprarenal glands sufficient carbohydrate to achieve the complete metabolism of the absorbed fat is in all probability the explanation of all these "bouts" or "turns," so variable in their individual symptoms. That in most cases the mobilization of the necessary carbohydrate is in the end successfully achieved spontaneously and somewhat suddenly, after an interval in which the child may suffer extreme distress, is in keeping with the hypothesis that the suprarenals have become temporarily exhausted. In many cases of severe cyclical vomiting, without any treatment at all,

the symptoms, which, up to a point, have been progressive and threatening, suddenly subside. There has been delay in the necessary mechanism for carbohydrate *mobilization*.

Ketonaemia.

Without sufficient carbohydrate the metabolism of fat is unable to proceed smoothly. Fat is, as it were, the reserve fuel, of which, unlike carbohydrate, there is plentiful storage. But fat can only serve as a satisfactory fuel, can only be metabolized completely, in the presence of a sufficient amount of carbohydrate. Without sufficient carbohydrate the process of reduction to oxygen and water is not completed, but certain intermediate products of combustion, the so-called ketone bodies, accumulate in the blood and are excreted for the most part by the lungs, but also, especially when present in great amounts, in the urine. The condition, commonly called acidosis, is therefore more strictly a ketosis, because although ketosis is a form of acidosis, yet it is only one of many varieties of acidosis.

The presence of ketone bodies in the blood produces further chemical reactions. When we speak of acidosis we do not by any means imply that the reaction of the blood has definitely moved to the acid side. We mean only that we are able to detect the shifts that the body is put to in its successful effort to prevent any significant alteration in the reaction of the blood. We recognize, in other words, that the reserves have been called into action. Only in states of great danger, in the presence of death itself, when these reserve mechanisms fail or become exhausted, is there an actual shift of the reaction of the blood to the acid side. The acid base balance is preserved by many and complicated devices, but that which plays perhaps the greatest part is the regulating power of the respiratory centre acting under the stimulus of the excess of carbonic acid in the blood. The acid ketone bodies combine with the sodium bicarbonate in the blood, setting free an equivalent amount of carbonic acid, which is then removed from the blood by the stimulation of the respiratory centre and the consequent increase of pulmonary ventilation. Hence in the condition known clinically as acidosis, besides a state of glycopenia with a blood sugar at a low fasting level, or even occasionally a definite hypoglycaemia, and besides a significant ketonaemia, there is found a diminution in the alkaline reserves of the blood, compensated for to some extent by an increased formation of ammonia.

In the need for increased pulmonary ventilation we have the explanation of the common complaint of the mother that the child is constantly yawning, sighing, or taking deep breaths. When the smouldering state of acidosis erupts into a definite bout of cyclical vomiting the onset is usually heralded in this way by much yawning and sighing. If we pursue this attempt to find some explanation of these common symptoms of physical and mental prostration we may perhaps attribute especially to the ketonaemia the extreme muscular relaxation, both of the skeletal muscles which shows in the flat-foot, the winged scapulae, and the lordosis with the too prominent abdomen, and of the vasomotor muscles which results in such striking pallor. The effect of the accumulation in the blood of these imperfectly oxidized fatty acids is in many ways comparable to the effect of chloroform anaesthesia, not only in derangement of the function of the liver, but equally strikingly in the profound muscular relaxation and vasomotor paresis. Through the toneless abdominal muscles of a child suffering severely from acidosis I have seen an intussusception reduced by manipulation with the greatest ease. Muscular relaxation more perfect for the purpose could not have been produced by profound chloroform anaesthesia. The muscular aches and pains, and the tendency to fall too readily, are secondary results of the amyotonia. It is, perhaps, not to be wondered at that the child with a persistent acidosis, with quick, rapid, and uncontrolled movements and toneless musculature, is more liable to suffer from greenstick fractures than are other children, not because the bones are softer or more brittle, but because the muscular support is poor and the child is incapable of making that sudden movement necessary to restore the balance, or at any rate to mitigate the severity of the fall. In "night terrors," in the comatose sleep of enuresis, and in the tendency to nausea and bilious vomiting we have further symptoms which bring to mind the similarity between the effects of chloroform and the effects of the ketone bodies in acidosis. The behaviour of a child struggling under light anaesthesia and of a child with night terrors are strikingly alike.

The Part Played by Infection.

Very often this state of prostration and of pallor is directly caused or greatly increased by some infection, and the removal of some persistent source of infection—as, for example, by tonsillectomy—becomes a necessary part of the treatment, not only of the state of acidosis but of the plentiful crop of nervous symptoms of one sort or another which thrive in this particular soil of acidosis. Infection is a potent and frequent cause of acidosis. Yet it is also true that acidosis, even in its mildest degree or in its incipient stages, powerfully predisposes to infection. The proneness of many of these pallid and lax children to trivial catarrhal infections adds greatly to the difficulties of their management, because, although the infection in itself may be of the slightest, the further disturbance of metabolism to which it gives rise is apt to be severe and persistent. In the total illness a trivial infective component may be altogether submerged in the metabolic component.

Acidosis and Asthma.

Nor is it enough to realize that acidosis predisposes to infection, and that infection produces a great exacerbation in the acidosis. An examination of a large number of children of this type will show many in whom it is clear that the disturbance of metabolism is itself capable of producing irritation and a catarrhal reaction in the mucous membranes lining both the bronchi and the bowel. In certain children mucous diarrhoea takes the place of vomiting as the most prominent symptom of the cyclical disturbance. In others, again, the main symptom is that of recurring attacks of bronchial asthma. We are reminded of a similar association in the so-called uraemic colitis and uraemic asthma. The part played by acidosis in the production of the asthma of childhood, or at least, if production is too strong a word, in the determination of the moment when an attack comes on, has not been sufficiently emphasized. A large number of children with asthma suffer at the same time from cyclical vomiting in greater or lesser degree. That there are other factors concerned in the production of the liability to asthma is clear, but it may well be that the danger point for an attack of asthma is reached, in the child so predisposed, when the blood sugar is at its lowest. Over-exertion, over-excitement, and infection are the main exciting causes in the cycle both of asthma and acetonaemic vomiting. In the part played by glycopenia we have, perhaps, the explanation of the tendency, common to both disorders, to nocturnal exacerbation. Asthma is apt to become worse at night; cyclical vomiting almost always begins at night. Such children stand even the physiological starvation of the night badly, and in the absence of a frequent intake of sugar the nocturnal metabolism is relatively unstable. The frequent combination of asthma with cyclical vomiting, or with some other manifestation of acidosis, is perhaps to be accounted for by the circumstance that both disorders occur almost entirely in excitable eager children who in action mobilize all their reserves of energy and suffer a corresponding exhaustion in reaction. In practice it is often found that successful control of the acidosis brings with it cessation of the asthmatic attacks, or at least a diminution of their number.

In the pale, exhausted, irritable, and nervous child suffering from, or about to suffer from, a "bout" or "attack," with or without vomiting, biochemical examination shows as a rule a blood sugar at a low level, if not a definite hypoglycaemia, ketonaemia, and a diminution of the alkaline reserves of the blood. In some children the attacks are very slight, in some very severe, but a study of the children and of their health from day to day and from month to month can leave no doubt of the essential identity of all the attacks, major and minor. In the same child not all the attacks culminate in vomiting. Many are, as it were, abortive. Nor do I think that there can be

any doubt as to the success of therapy based upon those biochemical findings—a reduction of the intake of fat to within the limits of the tolerance of the individual child, a freer intake of easily absorbed carbohydrate, and the provision of a daily depot of alkali.

Reduction of the Intake of Fat.

The reduction of the intake of fat need not, as a rule, be very drastic. There is, however, a natural tendency on the part of parents, made anxious by the extreme thinness of the child, to endeavour to improve matters by adding very considerably to the intake of fat. Cream or top milk and cod-liver oil are apt to be given freely, with the result that the trouble is increased and perpetuated. This is especially apt to occur when the fear of tuberculosis has been aroused. The propaganda in favour of a diet rich in fat receives support largely from observations upon the children of the poor, who, in general, are fed on much carbohydrate and little fat. The cost of sugar and starch per calorie is low, of fat high. Among the poor the ill effects upon this disorder of a diet too rich in fat are seldom apparent. Among the better-to-do they may be very evident. The omission of cream and cod-liver oil, the removal from a very rich milk of some part of the cream, the restriction of the intake of eggs and butter, perhaps to three eggs and a quarter of a pound of butter a week, may be necessary in households where the provision of milk, cream, butter, and eggs in large amounts has been considered the first essential for health and strength. Chocolate contains a high proportion of a fat which these children appear to tolerate especially badly, and should be omitted, as should all forms of sweets which are rich in fat. Radiostol or ostelin may perhaps usefully be prescribed to children whose intake of fat is restricted for the time being in this way. With improvement in weight and in colour the restrictions may be gradually removed. It is very evident that we have especially to consider the state of the child at the moment when the meal rich in fat is taken. When tired or pale, after exertion or excitement, or in convalescence from infection—when, as we may imagine, there is a state of glycopenia—fat metabolism may be especially unstable. One observant schoolgirl, having fallen prey to one of her attacks of sickness, wrote home to her mother that it was not the rehearsal for the school play which was responsible for her sad state, nor was it the dripping of which she had partaken freely, "it was eating the dripping after the play."

The Provision of Carbohydrate.

For children in the state described the provision of a free intake of easily assimilated carbohydrate is very necessary. Moreover, experience shows that if the nervous child is apt at times and in certain states to have a low tolerance for fat, there is, as a rule, a high tolerance as well as a high need for carbohydrate. Only by constant replenishment of the carbohydrate reserves can we prevent that wasteful and imperfect oxidation of the meagre store of body fat which manifests itself in the bout of acidosis with the sudden and extreme loss of weight. The digestion of carbohydrate is usually well accomplished. If we encounter difficulties they are concerned usually not with digestion, but with the dislike for sweet things. The natural desire for sugar, which is part of healthy childhood, is apt to be absent in these infant intellectuals, who may prefer the savoury to the sweet. On the other hand, many constantly make demands for sugar, demands which some parents, influenced by the propaganda against sugar, sternly repress.

Propaganda on health matters is apt to suffer from the disadvantage that in the process of the simplification necessary for popular understanding most of the truth is apt to disappear. A diagrammatic presentment without light and shade, and with no place for the exceptions to the general rule, is all that can be attempted. The child with an inborn tendency to acidosis is, in this respect, the exception, and an indiscriminate propaganda in favour of a diet with much milk and cream, and with little or no sugar, has worked steadily against him.

Meat, fish, green vegetables, and fruit may be given as usual. On one side we must supervise, and may have to restrict the intake of fat. On the other side we must raise proportionately the intake of sugars and starches. All cereal foods, wholemeal bread, rusks, oatcake, wheatmeal biscuits, sugar, jams, jelly, honey, and golden syrup may be given more freely than usual. Suet pudding consists of so much flour and so little suet that it is permissible. A reasonable amount of barley sugar, maple sugar, sugar candy, or boiled sweets may be given daily at meal-times.

The prescription of glucose in the form of a drink flavoured with fruit juice has been of real service. Glucose has several advantages over cane sugar as a means of replenishing the carbohydrate reserves. It is only about one-half as sweet as cane sugar; it is absorbed very rapidly into the blood stream from the upper alimentary tract, and has not the same tendency to cause a fermentative diarrhoea. Its use, too, seems less likely to be followed by the appearance of urticaria, a troublesome result in some children of the free administration of cane sugar. Given between meals it does not disturb appetite, and has something of the effect of a glass of wine in the resulting improvement in colour and sense of well-being.

In insulin hypoglycaemia, mental states of excitement, apprehension, and confusion, as well as muscular weakness, are controlled with astonishing rapidity by means of a few lumps of sugar. In these nervous children something of the same sort can be achieved, if less strikingly and in less degree.

The daily prescription of a small dose of alkali is often helpful. It is common to advise the intake daily of a teaspoonful of sodium bicarbonate. If, as is often the case, there is constipation, to the morning dose of glucose there may be added a little Vichy water or other laxative saline.

By dietetic regulation along these lines, and by the free administration of glucose and of a small amount of alkali, good results can sometimes be achieved. Often a very rapid increase in weight, and improvement in colour and energy, follow the subsidence of the state of acidosis. Sometimes the whole character of the child seems to alter for the better, so that ceaseless opposition and resistance, or timidity, or tearfulness disappear. There may be unmistakable improvement in such symptoms as night terrors, asthma, enuresis, train sickness, even stammering, as the general health improves and self-confidence returns. Almost always the more direct symptoms of the acidosis, the tendency to bouts or attacks of vomiting or diarrhoea, or pyrexia, are manifestly controlled. When no such fortunate result occurs, but the symptoms continue unabated, the explanation lies sometimes in the presence of some focal infection, and sometimes in a persistent failure of the management. Encouragement, rest, freedom from infection, and a high intake of sugar—these seem the special needs of the nervous child.

DIAGNOSIS OF CANCER OF THE COLON.

BY

C. J. MACAULEY, M.B., F.R.C.S.ENG.,

SURGEON, MATER MISERICORDIAE HOSPITAL, DUBLIN.

CANCER occurs more commonly in the colon than in any other part of the alimentary tract, with the exception of the stomach. Colonic cancer is, however, of the less virulent type—that is to say, its rate of growth is comparatively slow, invasion of the lymphatic vessels and glands is relatively late, while remote secondary deposits, such as liver metastases, are, save in advanced and exceptional cases, distinctly rare. *A priori*, therefore, we have here a favourable field for surgical intervention, a fact which carries with it a correspondingly serious responsibility. If we are to meet this responsibility fairly all our resources must be thrown into the effort to detect the cancerous lesion at the earliest moment.

THE DEVELOPMENT OF COLONIC CANCER.

It will perhaps make for clearness of description if we regard cancer of the large intestine as exhibiting, from the clinico-pathological aspect, three distinct phases.

1. *The Pre-cancerous Stage.*

In this stage a lesion is present which is capable of developing, and, if untreated, does ultimately develop, into a cancer. Recent work has shown conclusively that a very strong potentiality for malignant change is inherent in the simple intestinal adenoma. Cancer of the colon is invariably an adeno-carcinoma; its mode of origin in a selected area of bowel is described by Dukes as follows: first, the occurrence of small localized areas of epithelial hyperplasia from which arises a crop of adenomata; next, the formation of an adeno-carcinoma from one of these areas or in the neighbouring epithelium; finally, when the definite transition to carcinoma has been effected in one of these little tumours, a tendency to undergo retrogression in the others, which are, consequently, not prominent in the stage of developed cancer. The best instance of this change is seen in those rather rare cases of multiple adenomata (adenomatosis) which show a marked tendency to malignant transformation. Saint, in a study of the intestinal polypi, found that, in the large bowel, the sigmoid was by far the most frequent site of occurrence, and that the adenoma was by far the most common type of polypus encountered. If we compare Saint's figures with those of others showing the relative incidence of carcinoma in various parts of the colon, we find a remarkable correspondence. Saint's figures are: caecum 8, ascending colon 6, transverse colon 3, descending colon 5, sigmoid colon 20. Thus nearly 50 per cent. occur at the sigmoid. Burgess's figures give 55.3 per cent. and Brown's figures give 53.1 per cent. as the proportion of sigmoid cancers in the large bowel. We cannot help feeling that we may have here an explanation of why cancer occurs so much more frequently in the sigmoid than in any other part of the colon. Unfortunately, in the present state of our knowledge the clinical value of these facts is not very great. Apart from the rectum and lower sigmoid, adenomata have been recognized clinically only under two conditions. (*a*) In adenomatosis symptoms occur which are distinguishable from those of ulcerative colitis only by the use of the sigmoidoscope. It is useful to remember that this may be the real pathology underlying cases of ulcerative colitis. (*b*) The single polyp, unless it has undergone ulceration or has attained a considerable size, may first be revealed through the occurrence of an intussusception.

Recently a young woman was admitted to my wards with an intussusception involving the whole sigmoid, the starting point of which was a polypoid adenoma. A more striking case was that of a man, aged 69, who consulted me for recurrence of a rectal polypus which had been removed by another surgeon two years previously. I removed the growth, together with a portion of the bowel wall. The pathological report on the specimen was as follows: "The tumour is a papillary adenoma. The only sign of malignancy consists of mitoses; but as these are present in numbers the condition appears to be one of very early malignancy." This patient comes regularly for proctoscopic examination, so that should the cancer unfortunately continue to develop it will at least be recognized at a very early stage.

The more frequent use of the sigmoidoscope, especially in elderly patients, should, by revealing these adenomata so common in the sigmoid, enable us to lower considerably the incidence of colonic cancer.

2. *The Latent Stage.*

In this stage cancer is definitely present, but betrays either no sign of its existence or signs so vague and inconspicuous as not to attract the attention even of the patient. The pathological condition present in the silent period is either a cauliflower growth which has not yet begun to bleed or to ulcerate, or a constricting growth, the effects of which are being adequately compensated. This silent phase is, of course, an unfortunate characteristic of the early growing stage of internal cancer in any part of the body, but it is particularly unfortunate here in view of the relatively good prognosis which attends competent surgery in clinically recognizable cases. It is truly remarkable to what extent non-obstructing cancers of the colon can grow without producing definite symptoms, and it is not uncommon for the accidental discovery of a lump by the patient or by his medical attendant to be the first sign of disease. It is at this stage that the development of anaemia, which is an almost constant feature of cancer of the proximal colon, whether it occurs in youth or in adult life, is of special significance. Flint records the case of a woman who consulted her doctor on account of shortness of breath, when routine examination revealed a lump in her abdomen, which was subsequently proved to be a cancer of the proximal colon. She had suffered neither pain nor irregular action of the bowels, but was extremely anaemic. A precisely similar case occurred in my own practice. An analogous form of secondary anaemia is found also in cancer of the stomach. This common tendency to anaemia in gastric and caecal cancer gives an added significance to the anatomical description of the caecum as a "second stomach."

3. *The Stage of Observable Clinical Manifestations.*

At the outset it is necessary to realize that cancer of the colon takes two main forms with correspondingly distinctive effects. In one these effects are due to the presence in the lumen of the bowel of an ulcerating mass; in the other to the [illegible]g of the lumen by a constricting proce[illegible] is, of course, not always sharply defined, since an ulcerating growth may cause obstruction and a constricting growth may, and often does, exhibit some degree of ulceration. The broad difference nevertheless remains, and it is of the utmost importance that it should be borne in mind.

What are the effects of ulceration? If we visualize, for a moment, the presence of an ulcerating growth in the bowel wall it is clear that not only is the growth itself an irritant which the bowel seeks to expel, but that, as a direct consequence of its presence, new and deleterious elements are added to the intestinal contents. These are: (*a*) Excess of mucus from the cells of the tumour and from the irritated mucous membrane, a feature of which sometimes leads to the erroneous diagnosis of mucous colitis. According to Ochsenhirt mucus production in large intestine cancer is an indication of differentiation on the part of the growth, and he seeks to establish the postulate that the number of mucus-secreting cells in the carcinoma is inversely proportional to the grade of malignancy. (*b*) Small quantities of blood, due to traumatism of the ulcer face. (*c*) Septic material from the surface of the ulcer, which in such an environment cannot long remain free from secondary infection.

The combined result of the presence of an irritating growth and the local accumulation of irritant material is to cause an increase in the functional activity of the bowel—that is, increased frequency of peristalsis resulting in diarrhoea, which is mainly of the mucous type. Brown found diarrhoea in 36 per cent. of his proximal and distal colon groups, but, whereas in the former it was a true diarrhoea, in the latter it was rather tenesmus, attacks of which alternated with periods of obstinate constipation.

When colonic irritability of this kind sets in and persists in a person who has previously led a regular bowel life, the suspicion of cancer must be strongly aroused. This is especially true in very old people, in whom chronic diarrhoea is very frequently due to cancer. I would here advise caution against the dangerous diagnosis of colitis, which I have seen followed—as who has not?—after a regrettably long interval, by a palliative colostomy. Petrén records a case of a patient who, after treatment of three years' duration for ulcerative colitis, was found to have cancer of the splenic flexure.

There are other less direct but equally characteristic effects of the ulcerative process, and of these the most important is anaemia, which is especially characteristic of cancer in the proximal colon. So characteristic is it that the development of a severe secondary anaemia for which there is no obvious cause should direct attention towards the possibility of caecal cancer. There are two curious facts about this anaemia—one that it can, and does, occur without visible loss of blood, even in the absence of occult blood; the other, that it is not such a menace from the operative standpoint as might be expected, and is, in fact, no insuperable barrier to a successful resection. While

there has been a great deal of speculation as to its cause, there can be little doubt that it is largely due to constantly recurring loss of blood in small quantities from the growth, heightened by absorption of toxic material from the involved bowel. It has been shown that there is a definite relationship between the size of the tumour and the degree of anaemia, and it has been pointed out (by Alvarez) that caecal cancers are bathed in the most highly infective fluid to be found anywhere in the body—a fluid full of organisms, which, when injected into animals, produces severe anaemia. The intensity and constancy of this anaemia in carcinoma of the proximal colon may not unreasonably be correlated with the considerable absorptive powers of this part of the large intestine. Flint suggests, as a possible explanation, that urobilin may be normally absorbed from this region, and is altered in some way when disease starts here, so that it cannot take its proper part in the formation of haemoglobin. Whatever the explanation, the anaemia remains as a striking clinical fact.

In the case of an obstructing lesion the course of events is as follows. The narrowing of the lumen at the site of the growth tends to delay the faecal stream, but for a time compensation is effected by the hypertrophy of the bowel above the lesion. As the constriction advances, hypertrophy increases and the more vigorous peristalsis thereby induced results in colicky pains. These pains are attended by rumblings of flatus or borborygmi, and they are made worse by purgatives. Owing to the fact that they are often set in motion by the taking of food, they are frequently ascribed to dyspepsia. One of my patients had dieted herself to the verge of starvation for three months for an "indigestion" which was really due to cancer of the transverse colon. After a time, to the hypertrophy is added dilatation, which most markedly affects the caecum; and during attacks of pain visible or palpable peristalsis may be noted, which, when present, is pathognomonic of obstruction. If the ileo-caecal valve is incompetent the lower coils of ileum are affected by the hypertrophy and dilatation producing the characteristic "ladder pattern." Curiously enough, the patient can often locate accurately the site of the obstruction. As a result of stagnation in the dilated bowel the stools are usually very offensive, and intermittent attacks of diarrhoea are prone to occur. Sooner or later this obstruction becomes acute, being not infrequently precipitated by a purgative—the actual cause being congestion and oedema at the site of the stricture, the impaction of a hard faecal mass or foreign body in the narrow lumen, or, in the case of the mobile segments—sigmoid or transverse colon—to the occurrence of volvulus or intussusception.

Situation of the Growth.

So far we have considered in a general way the effects produced by the two types of growth which occur in the colon. Let us now see how the clinical picture is affected by the situation of the growth.

In the *proximal* colon the growth is usually of the fungating cauliflower type, and forms a definite mass. This mass is situated most frequently at the caeco-colic junction, and because of its bulk and its accessible situation is palpable at a moderately early stage. Ulceration, with its attendant train of symptoms—irritability and anaemia—soon occurs. Obstruction in this segment of the colon is rare, owing partly to the nature of the growth, partly to the fluidity of the intestinal contents, and in part also to the wider calibre of the tube. Alvarez found the diameter of the colon to vary (in Roentgenograms) from 6.5 cm. in the caecum to 2.5 cm. in the sigmoid. Brown found a palpable swelling in 68 per cent. of his proximal colon cases, and in only four cases did carcinoma of the proximal colon cause symptoms of obstruction, in two of which the obstruction was acute.

In the *distal* colon tumour is not often felt (Brown found it in 24 per cent. of his distal colon cases), and practically never in tumours of the splenic flexure, because of its fixed high position under the ribs. Some degree of obstruction is very frequent, owing to the encircling form of growth, the solid contents, and the diminished colon diameter. When the splenic flexure is involved obstruction occurs in practically 100 per cent. of cases.

In the *transverse* colon the growth may be of either type, but in the left end of the transverse colon the sclerosing form predominates, and in this segment, therefore, obstruction is common. A tumour, when present, is characterized by its extreme mobility. Owing to the juxtaposition of the stomach and great omentum, gastric complications are not unusual and the symptoms may be mainly of the dyspeptic type.

The general principle may therefore be stated, with due allowance for occasional departures from type, that in cancer of the left colon obstruction is the rule; in cancer of the right colon obstruction is the exception. Burgess's figures are 87 per cent. and 13 per cent. respectively. This marked difference in clinical behaviour is all the more noteworthy in view of the embryological distinction between the two segments. The right colon, as far as the splenic flexure, is developed from the primitive midgut in continuity with the small intestine, which it resembles in the fluidity of its contents, the absorptive power of its mucous membrane, and in the presence of a retarding mechanism (caeco-colic sphincter and antiperistalsis). The fluid contents make obstruction difficult even in the presence of large and sclerosing growths, while the characteristic anaemia is no doubt partly dependent upon its absorptive function. The left colon is developed from the primitive hindgut, and as the process of absorption is complete with the final loss of water in the transverse colon, it must be regarded mainly as an excreting organ. In view, therefore, of the fact that these two segments of the colon have different origins and different functions, it is not greatly to be marvelled at that they react differently to the carcinomatous process.

THE DIAGNOSIS OF COLONIC CANCER.

By what methods of examination shall we seek to establish the diagnosis of colonic cancer?

1. A careful anamnesis—with particular attention to the onset and persistence of a definite change in the patient's bowel habits from regular to irregular. According to the nature of the growth and the segment of the colon involved, the clinical picture will develop along the lines of an ulcerative or stenotic lesion. It must be remembered that loss of weight and energy occur only in advanced cases.

2. Physical examination. Among the signs or symptoms noted will be anaemia, visible or palpable peristalsis, local distension of the caecum, and in certain cases a palpable tumour. In experienced hands the ordinary stethoscope will often give information of value by demonstrating the gurgling of gas through a narrow opening. The ability of the patient to localize, in many cases, the site of the obstruction should be remembered. A rectal examination may reveal a recto-sigmoid growth when the patient strains, or ballooning of the rectum in the case of growths situated at a higher level. Bimanual examination, aided, if necessary, by a general anaesthetic, often gives information of value.

3. Examination of the stools for visible and occult blood, pus, mucus, and fragments of tumour tissue. In the case of occult blood repeated examinations should be made, a persistently positive finding being strong presumptive evidence of cancer. Hurst states that he has never seen a growth of the stomach or colon where occult blood was not present. Petrén found a positive Weber reaction in the faeces of 35 out of 44 cases examined, and emphasizes the value of a persistently positive Weber reaction in uncertain cases.

As the result of a complete general clinical examination the diagnosis of the site and nature of the growth may be fairly clear. In many cases, however, this is not so, and we must call upon two additional diagnostic aids—the sigmoidoscope and the Roentgen ray. For growth in the lower half of the sigmoid the sigmoidoscope is, in skilled hands, an instrument of the very greatest value, and no one should consider himself competent to handle those cases properly until he has made himself proficient in its use. It not only demonstrates a cancer when present here, but it enables us to recognize the characteristic lesions of ulcerative colitis, to identify papillomata and adenomata,

and, if necessary, to remove portions of tissue for examination. If we bear in mind the important fact that 50 to 55 per cent. of colonic cancers occur in the sigmoid the value of the sigmoidoscope should be readily appreciated.

For those numerous cases where ordinary clinical methods, even when aided by the sigmoidoscope, still leave us in doubt, we have an invaluable ally in the Roentgen ray, which is now justly considered to be the most valuable method of examination in colon conditions. In recent years the opaque meal as a method of colon examination has been almost completely superseded by the opaque enema. In many cases the meal has failed to show a cancer which operation subsequently revealed; this has resulted in negative findings being regarded as a snare and a delusion, with inevitable reaction upon the harassed radiologist. There was also the real danger of precipitating an attack of complete obstruction in stenotic lesions, through the inability of the bowel to rid itself of the barium. Since this happened in one of my cases I have ceased to order opaque meals for patients with suspected colonic cancer. Nowadays, however, with the more frequent use of the opaque enema, the whole picture has been completely changed, and we have at our disposal an agency which makes possible an accurate diagnosis in almost 90 per cent. of cases.

The examination must, of course, be carefully and skilfully performed if sources of error are to be excluded, and the findings must be checked by a second or even a third examination. If stenosis is marked, the enema may be completely arrested at the site of obstruction, thus affording conclusive evidence of blockage. If the enema passes the obstruction the characteristic filling defect with dilatation of the bowel proximal to the growth will be seen. Local spasm may be almost indistinguishable from organic narrowing, but if Carman's directions be followed—that is, administering the enema at considerable gravity pressure in conjunction with antispasmodics and forcible filling of the spastic segment by manual palpation—it is usually possible to make a differentiation. In a similar manner it is possible, with care and patience, to exclude the pseudo-filling defect caused by gas or extra-colonic lesions. Forty-one of Petrén's cases were radiographed, and in 30 of these the opaque enema gave a correct diagnosis; in 4 the appearances were doubtful, and in 7 they were negative. Of the 7 cases 4 could undergo radical operation. It is obvious, therefore, that a negative result must still be received with a certain amount of scepticism, even on repeated examination. In the best hands there is still a small residue of cases in which the *x* rays fail to reveal a growth which is actually present, but with improvement in technique and increase in the capacity for skilled interpretation these cases are becoming very few, and it may truthfully be stated that the opaque enema holds its place as the most reliable method of locating cancer in the colon. It cannot, however, be too strongly emphasized that radiography is only a part, albeit an important part, of the method of investigation. The findings must never be read alone, but only in conjunction with a careful clinical history and a complete physical and laboratory examination. If this is always done there will be very few cases in which we shall be forced to the crude expedient of the exploratory laparotomy, although this, our last line of defence, is one which we are perfectly justified in employing when, after exhaustion of our methods of clinical diagnosis, a reasonable doubt still remains.

DIAGNOSTIC DIFFICULTIES.

1. The ulcerating type of growth may be confused with inflammatory conditions of the colon which cause bleeding and the discharge of mucus and pus—for example, colitis (mucous and ulcerative), polyposis, etc. It is in these cases that the sigmoidoscope helps by revealing the actual lesion in the pelvic colon. In ulcerative colitis the rigid bowel wall will give the typical *x*-ray appearance of a straight tube devoid of haustration—the "ribbon-like" colon. It must, of course, be remembered that polyposis is rare, while cancer is common, and we should be very slow to make a diagnosis of ulcerative colitis of recent onset in an elderly person.

2. It is often difficult to distinguish between cancer of the pelvic colon and diverticulitis. In the latter, apart from clinical evidence of an inflammatory origin, bleeding practically never occurs, and the radiographic appearances are conclusive; these are: rounded, annular, or crescentic shadows projecting beyond the general line of the lumen of the bowel, and, after evacuation of the enema, parallel rows of opaque spots, due to retention of barium in the diverticula, are seen. Again, it should not be forgotten that cancer and diverticulitis may co-exist.

3. Cases with tumour in the right iliac fossa are to be distinguished from early actinomycosis, hyperplastic tuberculosis, and appendicitis. In actinomycosis there is a loss of weight and anaemia, but it generally runs a febrile course. The palpable mass is less definite in outline, and a radiogram may help to show its extra-colonic nature. In actinomycosis, however, as in hyperplastic tuberculosis, unless the clinical diagnosis is reasonably clear, we cannot expect much help from the Roentgen ray, and it is just in this type of case that we are often compelled to resort to operative exploration. Even at operation we may be unable to exclude cancer as the cause of the mass, and it is just here that the individual judgement of the surgeon, based upon his knowledge of what Moynihan calls the "pathology of the living," is of inestimable value in enabling him to recognize the true nature of the case. In appendicitis the short history and local evidence of inflammation should suffice to make the distinction. Strange though it may appear, the reverse mistake of treating a cancer as appendicitis is more likely to be made, the final post-operative diagnosis becoming painfully obvious as the sinus refuses to close and the mass increases in size—a clinical picture also seen occasionally in cases of actinomycosis.

4. Cancer of the transverse colon may be mistaken for chronic intussusception, owing to the existence of a movable tumour. An opaque enema will settle the diagnosis, the appearance after the evacuation of the enema in a case of intussusception being particularly striking. Here again one should bear in mind that a growth may be the cause of the intussusception.

In this paper I have dealt with the diagnosis of cancer of the colon before the onset of acute obstruction. At this stage it is possible to carry out a planned operation for the removal of the growth with the infected lymphatic area, at a mortality rate of about 10 per cent., and of the cases that recover about 25 per cent. are alive at the end of five years. When obstruction has supervened the operative mortality is about 35 per cent., and in many cases only a palliative operation is possible. Unfortunately the obstruction figures are still painfully high. Burgess in a total of 485 cases found acute obstruction in 173 (36.6 per cent.; Brown in 171 cases found it in 43 (25.7 per cent.); and Petrén in 50 cases found it in 21 (42 per cent.). In Brown's series the mortality was 30 per cent. for palliative operations alone.

The importance of making the diagnosis in the precancerous stage is but too painfully obvious, and the rate of diminution of the acute obstruction figures will be the best evidence of the success of our efforts.

STATE OF THE ARTERY AND THE CIRCULATION UNDER THE SPHYGMOMANOMETER CUFF DURING COMPRESSION.

BY

HARRINGTON SAINSBURY, M.D., F.R.C.P.,

CONSULTING PHYSICIAN, ROYAL FREE HOSPITAL AND CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

IT is generally assumed that the lumen of the brachial artery is completely obliterated when, in the course of a blood pressure estimation, the pulse at the wrist ceases to be palpable, and on the face of it this assumption appears almost to be self-evident. Moreover, has it not the sanction of physiologists generally? Consult here the figure in Starling's *Physiology* (1926, p. 806), also Howell's textbook (1927), and Gallavardin's figures reproduced in Halls Dally's *High Blood Pressure* (1926, p. 42)—nothing could be more categorical and plain to see. In spite of all this I have been driven to doubt the *fact*, and this doubt has grown in strength with further consideration. May I be allowed to produce my reasons? I must add that this is not an academic question for mere debate; it is a plain matter of fact or not, and it raises a definite practical issue in respect of the interpretation of the manometer readings.

Reaction of the Tissues to Compression.

To begin with, then, as we are dealing with compression and compressibility, it must be asked, Are the so-called soft parts of the arm—Gallavardin's *parties molles*—rightly thus named? They consist of adipose tissue, muscle fibre, and a fibrous framework which embeds and encapsules; further, of a system of vessels, blood- and lymph-containing, which ramify through the whole mass; we can probably omit the consideration of the last-named, the lymphatics, as negligible. Enclosing this tissue-complex is the dense exoskeletal structure of the skin, more or less loosely tied to the deeper parts, and, completing the list of factors which enter into the problem, there is the central core of bone, which presents its rigidity to serve for attachment as well as to supply a surface for counterpressure.

Now there will be no doubt in our minds as to the unyieldingness of the bony core; is there any as to the yieldingness of the "soft parts"? *Fiat experimentum*—thrust the thumb forcibly into the mass of the biceps; does it not sink in, and does this not settle the question? No, for another interpretation offers—namely, that within certain limits these parts are free to move and that the thumb has just thrust them aside; in other words, the experiment has shown displaceability—not compressibility—and it must be repeated, with displaceability ruled out. This can be effected most readily by enlarging the area of compression, and it is secured by the cuff of the sphygmomanometer, which not only covers a large area but envelops the whole circumference of the arm in its grasp. Thus conditioned, when the instrument is put into action do we as a matter of observation see any appreciable displacement of the soft parts either above or below the cuff, or does the cuff sink in, as did the thumb? Again the answer is No; a little puffiness above its upper edge and a similar slight puffiness below the lower edge, together with a moderate general tumefaction and a duskiness of the forearm, is all that is noted (the last-named appearances find their explanation in certain congestive circulatory effects). There is accordingly no evidence of a displacement of the parts from under the cuff, either distally or proximally, nor of a yielding of the soft parts to the pressure of the cuff. Gallavardin's figures have, therefore, no foundation in fact, and the term "soft" parts is a misnomer; all that the thumb and cuff experiments have established is that the tissues are more or less mobile—displaceable, but not compressible within the pressure range of the manometer.

On *a priori* grounds the same conclusion might have been reached, for of the parts in question the adipose tissue consists of a mass of cells filled with fat in the liquid state; while the muscle substance is so heavily hydrated that in the living state it exists as a jelly, more or less fluid; and the blood is a liquid, which, though eminently displaceable, *given the outlet*, not so favoured behaves like other liquids and resists enormous pressure, in comparison with which the 100 to 300 mm. of mercury of the manometer scale are absolutely negligible.*

The position, then, at which we have arrived is that under the conditions secured by the sphygmomanometer the immobilized tissues are incompressible; further, that, regarding their liquid and semi-liquid state, we are justified on physical grounds in assuming that they will behave like other liquids; consequently that any pressure applied to the surface of the imprisoned area under the cuff will be transmitted immediately, uniformly, and without diminution throughout the substance of the cuff segment of the arm, for at each stage of the investigation, as the column of mercury halts in its ascent, the opposing forces are equilibrated, and the problem before us becomes one of hydrostatics, such as is exemplified exactly by the Bramah (hydraulic) press.†

This brings us to the subject proper of this paper—namely, the state of the artery and the behaviour of the blood stream under the rising pressure in the cuff of the instrument. It will make for clearness if we consider these effects in the following order: (1) in the arm below the cuff; (2) in the arm under the cuff; and (3) in the arm above the cuff.

1. *Effects in the Segment of the Arm Distal to the Cuff.*

These will be just those of a ligature round the arm. The ligature is very broad and its constrictive force is developed gradually, but on neither of these counts does its mode of action differ from that of any other ligature, in that it impedes both the entry of blood into the segment in question and still more markedly its escape therefrom; for the thin-walled low-pressured veins, in particular those of the surface, will be the first vessels to feel and yield to the pressure of the cuff at its lower border, and the first squeeze of the ball should suffice to close them. The deeper veins would follow suit quickly, for the cuff pressure effectually prevents any displacement of the tissues of the forearm, and these, becoming at once incompressible, transmit rapidly the surface pressure to the deeper parts. The primary effect therefore is venous obstruction along the line of the lower border of the cuff, with consequent gathering of the blood behind the obstruction, a movement which must work backwards towards the capillary fields and through these to the arterioles, leading ultimately to more or less arterial overfilling—in brief, to a choked state of all the vessels. It will, however, be noted that this general congestion is predominantly venous, and further that the accumulation of blood will again be most marked in the superficial veins, because the loose skin offers less resistance than the deeper parts.

These effects will continue throughout the duration of the experiment, and the surcharged vessels, therefore, will oppose an increasing resistance to the entry of blood from the cuff segment of the arm.

2. *Effect in the Cuff Segment of the Arm.*

In contradistinction to the line of pressure (that of the lower edge of the cuff) which is responsible for the above-described effects, we must now regard the consequences of a broad circular area of pressure which the cuff lays upon the whole of this segment. The skin is now immobilized along with all the other tissues; everything outside the walls of the vessels is, therefore, incompressible, and so the full force of the cuff pressure is brought to bear upon the blood, which, though *per se* incompressible, is not only displaceable, but is in act of displacement along a given line—that of least resistance.

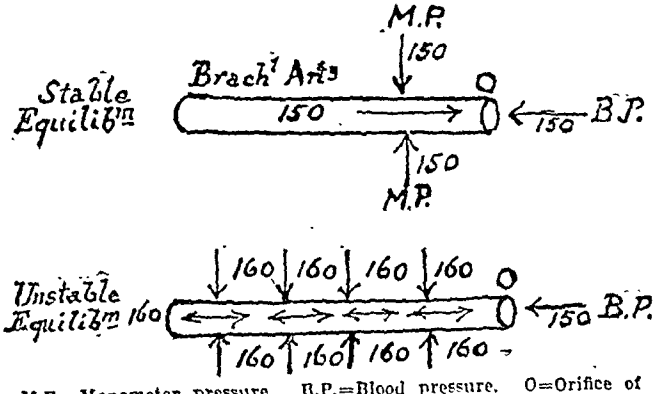
* Professor A. W. Porter of University College informs me that there are no data available as to the compressibility of bodies in the colloid or jelly state, but he holds it as almost certain that they will come close to liquids in their incompressibility.

† Exactly, in so far as the extravascular tissues of the arm are concerned, but through the blood vessels which permeate the tissues a flow of blood is all the while being maintained, and this complicates the physical problem, introducing a dynamic factor. However, this disturbing factor diminishes progressively as the experiment proceeds, and in the end, when the blood pressure is determined, it vanishes wholly with the arrest of the pulse.

Let us apply this to the state of things at the very commencement of the experiment. The blood is in actual movement through the vessels under a pressure which falls progressively from the arteries to the capillaries and from these to the veins, the ultimate destination of which is the right ventricle. Accordingly the internal blood pressure will be at its lowest, in this segment, at the mouths of the veins as they emerge from the upper edge of the cuff. Above this point the fall continues, and it is accentuated where the veins enter the chest by an actual *minus* pressure; there is, therefore, no impediment along this route; indeed, the *minus* intrathoracic pressure *favours actively* the centripetal flow. What, then, must follow when the encircling cuff begins to exert its grasp? The emptying of the veins must be accelerated, and in this process the superficial veins, which first feel the pressure, will take precedence. But very rapidly the surface pressure will be transmitted to the deep veins, and these will suffer a like emptying. An end to this depletion, however, must come as the walls of the veins flatten out and come into contact under the rapidly rising external pressure: thence onwards they are effectively sealed. How far back towards the capillary fields, or perhaps even into them, the emptying proceeds can only be determined by direct observation, for it is impossible to gauge *a priori* at what point the intra-arterial pressure which is striving to fill the veins will counterbalance the opposing pressure on the veins, which after the completion of the *forward* emptying process will now be directed *backwards*. Thus the primary effect of loading the surface of the cuff segment will be an emptying of the veins more or less, probably to a considerable extent —an effect exactly the opposite of that witnessed in the distal segment.

From the moment of the sealing of the veins, at this or that point, the circulation is interrupted up to the point of emergence of the veins from the upper edge of the cuff; but blood is still being squeezed into the arteries of the segment, though under increasing difficulties, so long as the intra-arterial blood pressure exceeds that in the extravascular tissues; the arteries, therefore, at this stage will perforce be all open.

The next step brings us to equality of the two opposing forces—that of the column of mercury in the manometer and that of the intra-arterial blood pressure; let us assume this to be 150 mm. The following diagram will represent the situation.



M.P.=Manometer pressure. B.P.=Blood pressure. O=Orifice of brachial artery at upper level of cuff.

Stasis is now complete, for no blood can enter the artery; *at the same time the artery maintains its patency*, for there is no surplus of force to compress its lumen, and we have before us a given volume of blood imprisoned between the orifice of the artery and the sealed veins. The problem has thus become one of hydrostatics pure and simple, which may be indefinitely prolonged, *ceteris paribus*. We must further note that along with the cessation of all movement of the blood the pressure throughout this fluid *is of necessity* equal in all the vessels remaining patent.

Let us now suppose that the next squeeze of the ball raises the manometer pressure to 160 mm.; what will happen? By an excess of 10 mm. the equilibrium will have become unstable, and this surplus is brought to bear upon the whole volume of blood; what will follow? The imprisoned fluid will seek an outlet, pressing equally in all directions, both peripherally towards the veins and centrally towards the heart *by way of the arteries*. But there is no thoroughfare peripherally, for there the sealed veins are held by the same excess of pressure as that which seeks relief. In like manner, at any given point along the vessels up to the brachial trunk itself, any attempt to shift the blood towards the veins will be countered—thus, up to the orifice O in the diagram, where an excess of 10 mm. finds itself unopposed. What then must follow, theoretically, is that the fluid will begin to dribble out backwards, reversing the normal circulation; there is no help for it.

In actuality a surplus force of 10 mm. in the face of the inertia of the *mass* of blood to be moved, against the surface resistance opposed by the multiple branching channels which contain it, would, without doubt, be imperceptible, certainly negligible; but, even so, we must note that a surplus of 10 mm. Hg (the apparent stasis still persisting) holds open the orifice at O. And actually, if we should push the experiment to a really appreciable extent—say to readings of 300 mm. or more—then an appreciable *expression of the blood* would be inevitable. But again what follows?—the orifice will still be *kept open* by the expulsive force until the last *quantulum* of blood has been driven out. Of course, the patency of the lumen of the vessels will, in that case, be gradually diminished as the volume of the blood to be expressed diminishes.

Within the time limits of a blood estimation, however, in which we should raise the manometer reading to 20 or 30 mm. above the pressure necessary for the extinction of the pulse, there will be no chance for these small surpluses of such short duration to effect any perceptible reduction of the volume of the imprisoned blood—the containing arteries therefore would remain fully patent.

On these grounds I am compelled to conclude that the *theory of an obliteration* of a section of the brachial artery in explanation of the extinction of the pulse is wholly untenable. I would, moreover, point out that any argument which could be brought forward in favour of th obliteration of the brachial artery by the outside pressur on its walls would hold equally for every other artery i the cuff segment of the arm, since its internal bloo pressure could not exceed that in the brachial artery But what force could conceivably shift all this blood, an where could room be found for it? Per contra if this is so if the arteries keep their patency throughout, how do w explain the extinction of the pulse at the wrist at a give moment, which is an indisputable fact?

A reasonable answer to this question is, I think, no far to seek, but it involves certain preliminary considera tions. The first is that the blood flow results from varia tions in blood pressure along the course of the vessels, an that this blood pressure is caused by the elastic stretc of the entire arterial system, but mainly, perhaps, by th elastic stretch of the aorta, which acts as a transforme between the power chamber of the ventricle, where all th energy is generated, and the capillaries. This actio resembles exactly that of the elastic bag of the Spra apparatus, which, interposing between the ball and th nozzle, converts the intermittent grasp of the hand int a continuous efflux from the nozzle.

The elastic stretch of the arterial system—in which how many ventricular systoles are summed up?—absorbs th whole of the cardiac energy, the intermittent generatio of which disappears quite by the time the capillaries are reached, and in the form of the elastic recoil it figures as the blood pressure, which measures the strength of the stretch. This is the sole cause of the blood stream. The fingers on the artery take no cognizance of it except as to the volume of the stream and the intravascular tension.

The pulse, on the other hand, is a manifestation of an entirely different order; it plays no part in forwarding the blood; it is an epiphenomenon, something superadded, and, seemingly, both unproductive and undesirable; for while it carries force in its progress along the arteries, the force is not available for circulatory purposes, yet it subjects the arterial wall to an additional strain, which may and does become a danger in disease. In a certain sense it runs counter to the purpose of the elasticity of the arterial wall, for it makes to reappear an intermittence which the elasticity has been at pains to suppress. In brief, it is

a percussion wave, which, arising at the aortic orifice, *quodam modo*, courses through the arteries at the rate of about 7 metres per second, whereas the blood stream is never faster than 0.5 metre per second.*

It must be obvious that these two velocities cannot be effectively harnessed to the end of one co-operative act. That which the finger on the artery takes note of, then, is the passage of a wave, and the impression gained is that of a lift, which is confirmed by physiologists, who teach that in the act of passing the artery is *expanded and lengthened*. Evidently the wave carries force.

Now let us take the stage of equipoise between the intra-arterial pressure—that is, the pressure caused by the arterial elastic recoil—and the opposing manometer pressure, when stasis supervenes; the pulse wave will, of course, present itself as usual at the mouths of the arteries, which are all open. Will it enter as usual? Why not?—it carries force; what is there to forbid? Well, there is no current to carry it. The answer to this is, it needs no current; it is not conveyed; it rides the blood stream and forces its way. We know that the percussion wave started by the cast of a stone travels as freely along the surface of a standing pool as over the smooth surface of a river, and in all directions, even against the stream. It will, therefore, enter and must reach the wrist, as usual, since the elasticity of the containing walls is not exhausted.

And now let us give another squeeze of the ball; the manometer rises, say, 10–15–20 mm., but the pulse is suddenly gone—why, if the arteries are still patent? For the simple reason that this new rise of extravascular pressure, caused by the squeeze of the ball, will then have sufficed to meet and cancel the expanding force value of the pulse wave; the arterial wall will thus be prevented from yielding and the wave cannot pass, though the channels are all open. This is the reasoned explanation now proffered to show that it is not necessary to invoke obliteration of the artery, to account for the extinction of the pulse at the wrist, in the process of taking the blood pressure; and in the foregoing I have endeavoured to demonstrate that on physical grounds the obliteration hypothesis is untenable. It remains that the reasons advanced should be tested.

Bacon has said: "*Visio oculorum melior est quam progressio animi*," which I suppose may be rendered "the sight of the eyes is better than the mental process"—that is, ratiocination—and one must agree that a simple act of perception would save much excogitation and debate. But in the absence of sight by the external eye (for who has seen the closed artery?) what remains but the mind's eye to probe the validity of a hypothesis which is, as it stands, a pure assumption?

It has been said that the subject is not merely academic in that it raises a definite practical issue—namely, that from the beginning of the use of the sphygmomanometer—on the assumption of arterial obliteration, it has been a moot point what proportion of the pressure readings is to be allotted to the intra-arterial tension, and what to the resistance of the arterial wall itself (this latter a very variable quantity, when in disease the artery becomes thickened and hardened). Persistent patency of the arteries would eliminate this question once for all.

* Compare Starling, op. cit., fourth edition, p. 819; also Wiggers, *Circulation in Health and Disease*, 1923, p. 190.

ILEO-CAECAL VOLVULUS FROM ADHESIONS FORMED BY LEFT-SIDED PELVIC APPENDICITIS.

BY

W. A. COCHRANE, F.R.C.S.Ed.,

HONORARY ASSISTANT SURGEON, ROYAL INFIRMARY, EDINBURGH.

THE following case is of interest in regard to diagnosis and development. Moreover, it is a commentary on the dangers of incomplete anchorage or fixation of a viscus that has been hitherto free.

The patient, a spinster aged 33, was admitted to hospital as an acute abdominal emergency. Twelve hours previously she had been seized by violent griping pains in the left lower abdomen, accompanied by vomiting. No flatus had been passed since the onset of the attack, and the bowels had moved on the day before the attack. There had been no menstrual irregularity. There was a history of chronic constipation and occasional attacks of indigestion, confined to the region of the left iliac fossa.

The patient did not look ill. The temperature was normal, and the pulse rate 96 per minute. The tongue was furred. The abdomen was scaphoid and characteristic of the slender congenital visceroptotic type of anatomic structure. It moved freely on respiration, and some distension was present. The patient complained of pain in the left iliac fossa. There was deep-seated discomfort on pressure in this situation, but no tenderness or muscular rigidity. Pelvic examination was negative, as also was the obturator test for pelvic appendicitis. Succussion was present about the umbilicus, a sign of the greatest importance in the early stages of obstruction of the small intestine.

The case was regarded as one of acute intestinal obstruction. The abdomen was opened by a mid-line infra-umbilical incision. Coils of ileum, moderately distended, were packed off. The pelvic colon was empty. The caecum and appendix were not in the right iliac fossa. The ascending colon, longer and much more mobile than the normal, being provided with a mesentery, was traced into the pelvis. The caecum was lying in the true pelvis, distended and completely filling it. Attempts to extract it from the pelvis were resisted until adhesions binding down the appendix to the left side of the true pelvis had been divided. In delivering the incarcerated caecum a volvulus of the ileo-caecal segment of the bowel was discovered. Rotation in a clockwise direction had taken place through more than half a circle, round the axis of the appendix, adherent to the left side of the pelvis. The bowel was quite viable. After correction of the volvulus the appendix was removed and caecal plication performed. The patient made a good recovery.

The caecum and ascending colon were extremely mobile in this case, being provided with a long mesentery. Such a state of affairs is not uncommon in the slender congenital visceroptotic type of individual. The caecum was thin-walled, atonic, and dilated, thus showing commencing failure of compensation, from long-standing difficulty of emptying. The appendix was cicatrized in its terminal portion, and the lumen in the distal half nearly obliterated. Obviously it had been affected by former inflammation. The previous attacks of left-sided abdominal pain supported this finding. Ultimately the appendix became fixed by adhesions to the left side of the pelvis. The hitherto mobile caecum became thereby insecurely tethered, and volvulus of the ileo-caecal segment took place.

Interest in atypical cases of appendicitis is sometimes associated with abnormal positions of the caecum and large intestine due to errors of rotation and fixation. The errors of mal-rotation and non-rotation of the midgut loop are those most likely to undergo volvulus change, and are usually, though not always, met with in the childhood period. In the adult it is the errors of the third stage of rotation, in which the viscera find their ultimate position of fixation to the posterior abdominal wall, that occur. Premature or high fixation of the caecum or failure in elongation of the colon results in an undescended caecum. Appendicitis in such a case may be difficult or impossible to distinguish from cholecystitis. Deficient fixation or abnormal elongation of the colon results in the low pelvic type of caecum. In the present case the attacks of appendicitis were atypical, being pelvic and left-sided. Intussusception in childhood and visceroptosis in the adult are intimately associated with this type of anatomical structure. Ileo-caecal volvulus is also associated with a low pelvic type of mobile caecum. To the incomplete fixation of the caecum produced by the adhesions around the appendix is to be ascribed one of the exciting factors concerned in its production in the present instance.

The case is an interesting example of an anatomical structure varying quite definitely from the normal, but which functioned fairly well until the introduction of another factor led to serious risk to function and to life. Nature's incomplete efforts at "caecopexy" were certainly disastrous in this case. May it not be argued, therefore, that fixation operations are essentially unphysiological in congenital visceroptosis? It seems to me that they are based upon an incomplete understanding of the altered anatomical structure and function of the individual as a whole. General methods of physical education and support would seem to meet the need in the majority of cases.

THE TREATMENT OF TUBERCULOSIS OF THE LUNGS BY SANOCRYSIN.

BY

WILLIAM STOBIE, M.D., M.R.C.P., AND SHEILA HUNTER, M.A., M.B., CH.B., D.P.H.,

HONORARY ASSISTANT PHYSICIAN, RESIDENT MEDICAL OFFICER,

OSLER PAVILION, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL, OXFORD.

IN these notes we do not propose to say anything on the history of sanocrysin since its introduction by Moellgaard in 1923. The story of its discovery, with the early method of its employment and subsequent modification, is readily available in the now extensive literature. Our purpose is to relate our experience of its use in 45 cases during the past two years, with special reference to the most suitable type of case for treatment, the dosage and length of treatment, and to give our conclusions as to its value as a therapeutic agent in pulmonary tuberculosis. As the various complications are now so well recognized they are merely mentioned in passing.

In all cases tubercle bacilli were present in the sputum at the beginning of treatment. This point is stressed since so often various treatments have been apparently successfully employed in tuberculosis in the absence of unequivocal proof of its presence. The value of early treatment in "closed" cases is not disputed, but for scientific records it is essential that there should be no shadow of doubt as to diagnosis.

All the 45 cases were in Stage II or Stage III, mostly the latter, and in all there was a preliminary period of routine (sanatorium) treatment without definite improvement. All the patients were under sanatorium regime during treatment.

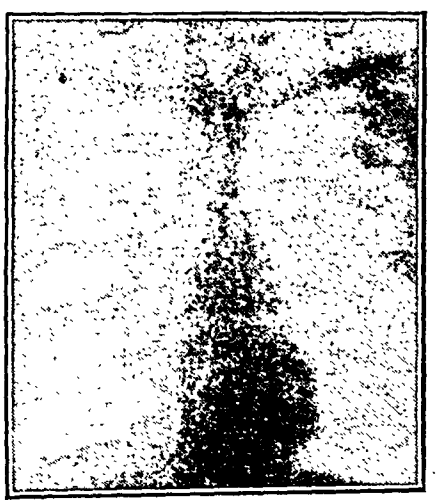


FIG. 1.

FIG. 2.

Selection of Suitable Cases.—It has been abundantly shown that the type of case most likely to benefit by sanocrysin is that showing the "exudative" variety of lesions. This type is recognized on the *x*-ray film by the fluffy, wool-like appearance of the areas of density generally scattered through both lungs. (Fig. 1.) This contrasts with the sharper and more defined areas of density, often unilateral, in the fibroid type of the disease, and frequently accompanied by old cavitation. (Fig. 2.) These differences are easier to determine on the *x*-ray films than in reproductions. Certain cases may show densities of both recent and old-standing disease.

Clinical Signs.—On clinical examination in the first (suitable) type there is only slight impairment of percussion note and weak breath sounds, with medium-sized crepitations; whereas in the second (unsuitable) type are found shrinkage, marked dullness, loud bronchial breath sounds, and consonating rales.

Contraindications.—The following are the chief contraindications. (1) Cases of fibroid phthisis. (2) Cases with gastro-intestinal symptoms. (3) Cases with symptoms of marked toxaemia—for example, fever above 101°, profuse night sweats, rapid emaciation. (4) Renal disease (sanocrysin produced slight evanescent albuminuria in the majority of cases). (5) Any other systemic disease—for example, diabetes.

Sanocrysin must only be given cautiously, if at all, to patients complaining of abdominal pain or loss of appetite. Vomiting, diarrhoea, and loss of weight are common complications of this therapy, and are especially apt to occur in these cases.

Case 1.—Male, aged 20. Appetite poor; steady loss of weight. As the appetite was improving sanocrysin was given. On the day following the first dose the patient complained for the first time of "indigestion." On the day after the third injection (0.125 gram only) the patient had diarrhoea and abdominal pain. Both these symptoms became worse and sanocrysin had to be abandoned. Previous to treatment by sanocrysin the patient was inclined to be constipated.

Indigestion *per se*—that is, epigastric pain after food, flatulence—is not a contraindication. The gastro-intestinal symptoms referred to above in all probability represent a manifestation either of abdominal tuberculosis or come under Group (3).

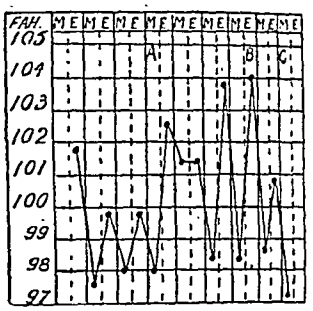

CHART 1.—A, 0.05 gram sanocrysin (fifth injection of same amount). B, Antipyretic treatment. C, Sanocrysin discontinued; no definite increase in focal signs.

Case 2.—A boy, aged 12, with signs of disease in both upper lobes, more extensive on the left side. The temperature before injections were given was 98° to 101° F. After two injections (0.05 gram) there was no change. It was higher after the third and fourth injections of the same amount, and still higher after the fifth injection (see Chart 1). This increase of reaction suggests a cumulative effect of the drug. There was no increase in focal signs, but treatment was abandoned because of the hyperpyrexia. The patient died several months later.

Tuberculous laryngitis is not a contraindication; on the contrary, it tends to improve under sanocrysin therapy. In one of the cases under review there was a granuloma (lupus) of the epiglottis. This condition improved greatly with sanocrysin alone, no local treatment being applied.

Mode of Action.—The apparent action of sanocrysin is especially interesting to anyone familiar with the use of tuberculin. Following the administration of sanocrysin there may be the same rapid rise and fall of temperature as occurs after a diagnostic injection of tuberculin. A focal reaction is also not uncommon, and, as with tuberculin, it is very difficult to say how far its effect is harmful. It has been shown by various writers that there is frequently a rapid breaking down of tissue and cavity formation after the use of sanocrysin. Is it possible that this may be accompanied by the liberation of tuberculin?

Advantage over Tuberculin.—A great advantage of sanocrysin over tuberculin is the possibility of its use in cases of moderate pyrexia where tuberculin would be inadmissible.

Disadvantages.—(1) Expense is a grave disadvantage, an average course in this country costing about £4 5s. for the gold salt alone. (2) Close observation is necessary; this militates against the use of the drug by the general practitioner. (3) Patients weary of the more or less complete confinement to bed for the duration of the treatment, and may, in fact, refuse to continue treatment on this account. As a consequence, for the past six months we have allowed patients whose pulse rate and temperature are within normal limits and who are free of any adverse effect of the drug to get up for from two to seven hours daily. Patients remain in bed, however, on the day of the injection and the day following. As far as we can see, no bad results have been caused through this latitude.

An increase in pulse rate is regarded as of more importance than a rise of temperature, and in our opinion is a valuable factor in the consideration of prognosis. At the Osler Pavilion the practice has been gradually evolved of giving small initial doses, increasing slowly and steadily,

avoiding, as a rule, reactions greater than one degree. Chart 2 illustrates the case of a woman, aged 33, who did extremely well on sanocrysin and who yet always had a rise of temperature of about 2°. How to control these temperature reactions is one of the many problems in sanocrysin (and tuberculin) therapy. Anything severe in the nature of systemic disturbance, such as albuminuria or diarrhoea, should be avoided, and if these or other complications occur further doses should not be given before they have cleared up.

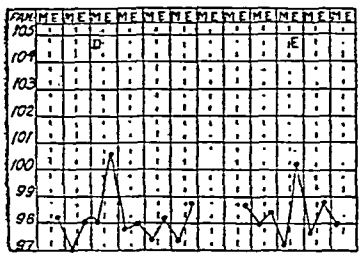

CHART 2.—D, 0.35 gram sanocrysin. E, 0.45 gram sanocrysin.

The dosage of an average course would be somewhat as follows, modified, of course, according to the reaction; the drug is given intravenously at weekly intervals—for example, 0.05, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.75, 0.85, 1 gram, the last dose being repeated two or three times. In female patients, as a general rule, 0.75 gram is the highest dose given, and is repeated once or twice. The average total amount given (exclusive of those cases where the treatment had to be abandoned for various reasons) has been approximately: men, 6.1 grams (10 doses); women, 5.8 grams (13 doses). Frequently reactions become more severe with the larger doses, and renal, gastro-intestinal, or skin complications develop, necessitating cessation of treatment.

Loss of weight quite often occurs, and may be considerable, causing interruption of treatment. As a rule the weight is quickly regained. It is unusual for a course to be completed without some reaction. Malaise and headache are frequently complained of, and drowsiness occasionally. In several cases treatment had to be abandoned because of complications which persisted.

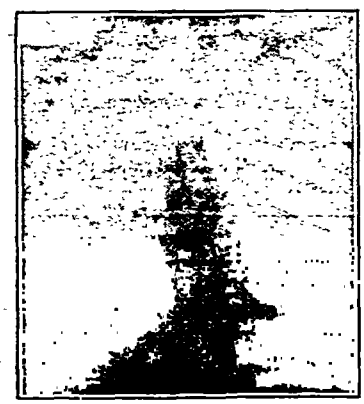

FIG. 3.

In the majority of cases the physical signs appear to have cleared more quickly than in all probability they would have done otherwise, although at first there may have been an apparent increase. This improvement is verifiable by x-ray films (see Figs. 3 and 4). In this particular case these were taken at an interval of less than three months. In these photographs an effort has been made to standardize, as far as possible, the time factor, the distance of the patient from the tube, the strength of the current, and the development of the films. The sputum eventually tends to decrease, although at first it may increase, especially in patients who have had little sputum. Tubercle bacilli disappear in most cases, though unfortunately they frequently, in fact generally, return some weeks after cessation of treatment. On the other hand, the physical signs, and more especially the general condition, appear to improve, and continue to do so after the treatment has ceased, which may be regarded as due to a cumulative effect of the drug.

Results of Treatment (45 Cases).

Definite improvement (physical signs and general condition)	25
Improvement but subsequent relapse...	2
Treatment abandoned (complications and general condition)	10
Treatment not completed (patient left hospital) ...	3
No improvement (worse 3, unaltered 2)	5

It would perhaps be more correct to add the 10 patients in whom treatment was abandoned to the 3 classified as worse.

Illustrative Cases.

In the following notes L represents the extent of the lung lesion, and S the degree of systemic disturbance as evidenced by the temperature range, or even more by the pulse rate. This classification is modified from that of Philip.

Many of the cases admitted to the Osler Pavilion during the past two years have been of the acute bronchopneumonic type, with an illness of short duration, following so-called influenza. How far this conforms to admissions in other areas we are not in a position to say.

Cases Much Improved.

1. A girl, aged 18; admitted December 20th, 1927, with extensive involvement of the left lung and upper right zone; onset June, 1927. The evening temperature was 101° F., pulse 76 to 96; L3, S3. She received in all 3.45 grams of sanocrysin, and was discharged on May 2nd, 1928; L2, S1. She gained weight under treatment. The sputum was always scanty; none on discharge. December, 1928: Condition satisfactory.

2. A youth, aged 19; admitted October 29th, 1927; onset "influenza" and pneumonia, March, 1927. Extensive signs in left lung and right upper zone; the larynx was slightly affected. Evening temperature 99° F., pulse 84 to 100; L3, S2. The disease progressed in spite of routine treatment and tuberculin. The total amount of sanocrysin given was 6.7 grams. He was discharged on September 21st, 1928; the physical signs, x-ray appearances, and larynx had all improved. The sputum was scanty, but still positive. December, 1928: Condition satisfactory.

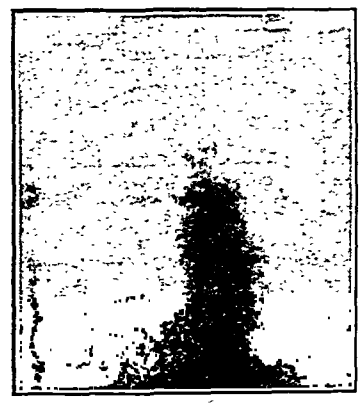

FIG. 4.

3. A man, aged 22; admitted March 12th, 1928; onset, summer, 1927, with lassitude and cough. Extreme lassitude and cough were the chief symptoms. Both upper zones were affected—L3, S3. The evening temperature was 100° F., pulse 95 to 112. He was given 5.8 grams of sanocrysin. On discharge L2, S1; a few bacilli were still present in the sputum. The physical signs and x-ray appearances showed definite improvement; the lassitude had gone. December, 1928: Condition satisfactory.

4. A girl, aged 12; admitted August 9th, 1927; onset "influenza," Christmas, 1926. The evening temperature was about 100° F.; pulse 80 to 100. There were extensive signs in the right upper zone; the chief symptoms were cough, anorexia, and lassitude. In all, 9.575 grams of sanocrysin were administered. The loss of weight towards the end of the course was quickly regained after its completion. On her discharge the sputum was scanty and negative. December, 1928: "Holding her own."

In view of the well-known evil prognosis at this age this case is regarded as satisfactory.

5. A girl, aged 18; admitted November 21st, 1927; onset September, 1927. Both upper zones were affected. The evening temperature was 99° F. L2, S1. She was given 4.3 grams of sanocrysin, and, after an interval of eight weeks, a further 2.95 grams. Sputum, which had always been scanty, was absent on discharge. The physical signs were much improved.

6. A woman, aged 22; admitted January 31st, 1927; onset November, 1926. The left upper zone and right apex were involved; L2, S1. The evening temperature was 99° F. She improved on routine treatment, but subsequently developed an increase of physical signs in one lung, with an evening temperature of 100° to 102°. She received a total of 8.25 grams of sanocrysin. When discharged, on January 23rd, 1928, the physical signs had improved, one or two isolated and broken down bacilli were seen.

7. A man, aged 39, admitted February 2nd, 1928; onset, haemorrhage, January, 1927. There was extensive disease of the left lung, and right upper and middle zones; L3, S1. The evening temperature was subnormal, pulse 76 to 92; sputum 6 oz. Sanocrysin to a total amount of 4.9 grams was administered. He was discharged on July 13th, 1928, with the physical signs much improved, and the sputum scanty and negative.

8. A man, aged 35, admitted February 21st, 1928; onset December, 1927. There was extensive disease of the left lung and slight disease of the right; L3, S3. Temperature swinging to 101° F., pulse 95 to 116; sputum scanty. He was given 5.35 grams

of sanocrysin. He was discharged on August 15th, 1928, with a normal temperature and pulse 72 to 92; there was no sputum. The physical signs and x-ray appearances were much improved.

9. A woman, aged 33; admitted March 3rd, 1928; onset December, 1927, "influenza." Most of the right lung was affected, and the left middle zone; L3, S2. Sputum was scanty. Evening temperature 99° F., pulse 84 to 120. She received a total of 4.5 grams of sanocrysin. When discharged, on June 5th, 1928, there was no sputum and the physical signs were much fewer; the improvement had been very rapid in a short time.

10. A woman, aged 24; admitted October 29th, 1927; onset August, 1924, pleurisy. There was extensive disease on the right with cavitation, and slight disease on the left; L3, S2. Sputum 3 to 4 oz. The evening temperature was 99° F., pulse 88 to 108. She was given in all 6.6 grams of sanocrysin. She was discharged on April 12th, 1928, with the physical signs much improved, sputum 1/2 oz., bacilli fewer but still present. The general improvement was maintained. She was readmitted on October 20th for a second course of sanocrysin (3.6 grams). When discharged, on December 22nd, there was further improvement in the physical signs and the sputum was negative.

Cases in which Patients became worse and where the Disease was probably aggravated by Sanocrysin.

11. A woman, aged 34; admitted June 25th, 1928; onset February, 1926. L3, S3. There was extensive disease of both lungs. The evening temperature was about 100° F., pulse 88 to 108. Small doses of sanocrysin were given after the temperature had been allowed to settle. After the fourth injection the patient had haemoptysis with fever (see Chart 3). There was no previous history of haemoptysis. The physical signs had increased.

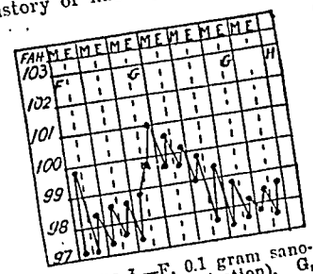

CHART 3.—F, 0.1 gram sanocrysin (fourth injection). G, Haemoptysis. H, Signs of extension of disease.

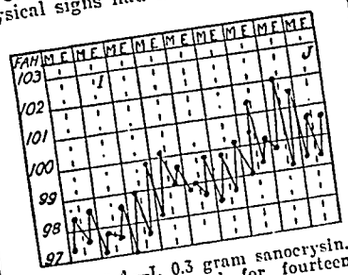

CHART 4.—I, 0.3 gram sanocrysin. J, Fever continued for fourteen days longer.

12. A woman, aged 22; admitted May 3rd, 1928; onset December, 1926. L3, S2. Pulse 96 to 132. The left lung was extensively involved, and the right upper zone was affected. Dermatitis occurred after the second injection, and treatment was stopped for four weeks. Seven doses were then given at weekly intervals. The temperature was rarely above 99° F. After the last injection the temperature began to rise and the patient had a continuous pyrexia with increase of physical signs (see Chart 4).

Conclusions.

We recognize the possible fallacies in attempting to draw conclusions in a disease where the unexpected so often happens, even in the absence of any form of treatment, and especially where more than one form of treatment has been employed. But after mature consideration we feel justified in making the following statements.

Sanocrysin cannot be regarded as a specific in the treatment of pulmonary tuberculosis. In suitable cases it shortens the period of routine treatment—that is to say, a similar degree of improvement may be obtained in considerably less time with sanocrysin than without.

With sanocrysin there is a greater possibility of the improvement following institutional treatment being maintained than there is without its use.

In carefully selected cases it is of value as an adjuvant to other methods of treatment. It is of definite worth in clearing the "better" lung in bilateral disease and allowing the establishment of an artificial pneumothorax on the "bad" side. It may also be employed with advantage in collapse therapy, of any variety, when there is a tendency for the "good" side to break down.

Used with care it is of value in the treatment of the acute exacerbations in chronic fibroid disease.

By ridding the sputum of bacilli even for a short time it must—theoretically, at any rate—limit the spread of the disease.

Sufficient time has not yet elapsed to allow us to dogmatize on the permanency or otherwise of the improvement.

CASES OF DIABETES MELLITUS WITH A LOW RENAL THRESHOLD.

BY

R. D. LAWRENCE,* M.D., M.R.C.P.,

CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL.

THE renal threshold, or leak point of the kidney for sugar, is usually about 0.17 to 0.19 per cent. blood sugar, and variations are recognized to occur in diabetes mellitus. Most commonly any change consists in a raising of the threshold above 0.2 or even 0.3 per cent. blood sugar, with the result that urine tests for sugar give little indication of the satisfactory control of the disease, making the patient appear sugar-free when the blood sugar is high. Much more rarely diabetes has been reported to be complicated by a lowered renal threshold. One case each has been reported in the last two years by Voigt,[1] Shapland,[2] and by Curran and Mills,[3] their articles leaving the impression that the combination of diabetes mellitus and a lowered renal threshold is a very rare condition. Consequently the following eight cases seem worth recording, as the condition leads to confusion and difficulty in the practical management of the cases.

Diagnosis of the Condition.

This presents no difficulty when a case of diabetes is being followed by blood, as well as by urine, sugar tests. As the result of treatment it is found that, whereas the blood sugars are becoming normal, the urine does not become correspondingly sugar-free. Positive proof that the renal threshold is abnormally low can be obtained by simultaneous tests of the blood and urine for sugar on one or two occasions. For example, after insulin has been given at 8 a.m. the blood and urine sugar may be tested as follows:

Time:	10 a.m.	11 a.m.	12 noon.	1 p.m.
Blood sugar per cent. ...	0.19	0.12	0.085	0.080
Urine sugar	+++	++	trace	0

This proves that the threshold is below 0.12 per cent., but not so low as 0.08 per cent. The condition can often be proved quite definitely by estimating the blood sugar only once and testing the urine secreted afterwards. In the above example the leak point could be proved to be below 0.12 per cent. by finding sugar in the urine passed at noon after the bladder had been emptied at 11 a.m.

Description of Eight Cases.

An individual description of these eight cases seems unnecessary. All the patients had had typical symptoms of diabetes mellitus and in all an abnormally high blood sugar had been found, either on ordinary diet or after a glucose tolerance test. In three cases diet alone controlled the blood sugars; in five insulin was necessary. Five were males and three females, and their ages varied from 19 to 68. In two cases there was a family history of diabetes.

The son, aged 14, of one of these patients has no symptoms of diabetes, but on two occasions has shown an abnormally high blood sugar curve with slight delay in the return to normal. Unlike his father, this boy has a raised renal threshold and passed no sugar at a blood sugar concentration of 0.225 per cent.

The level of the renal threshold was fairly closely observed in these cases, and was respectively 0.15, 0.14, 0.11, 0.1, 0.09, 0.09, and 0.08 per cent. It is obvious that the last few cases were hardly ever free from traces of sugar in the urine. The amount of glycosuria was in every case related to the level of the blood sugar, and the more the latter exceeded the threshold the more sugar appeared in the urine. This is contrary to what is usually stated to occur in renal glycosuria in non-diabetics, where

* Working on Insulin for the Medical Research Council.

the amount of glycosuria is said to be usually constant and independent of diet and the level of the blood sugar. This has not been true, however, in my experience of non-diabetic renal glycosuria.

In two of these diabetics the lowered threshold has remained constant for five years, and in none, observed over shorter periods, has it been found to vary. There is every reason to think, therefore, that the peculiarity is a permanent one, as renal glycosuria seems to be.

In addition to these eight cases, a lowered threshold appeared temporarily during pregnancy in two diabetic women, but became normal again after labour.

Practical Importance of the Condition.

These cases seem, on the whole, to follow the same course as diabetes with a normal renal threshold. They have not seemed more liable to ketosis than other cases, because they have not lost sufficient sugar in the urine to affect materially the ketogenic-antiketogenic ratio of the diet as fed. But one of the pregnant women, who was losing some 30 grams of sugar a day by the third month of pregnancy owing to the low threshold, excreted more ketone bodies than previously. The fasting blood sugar level might have been expected to be lower than usual from the loss of sugar, but this was not noticeable. However, two of the youngest patients, who had for years after the original discovery of their diabetes paid little attention to their condition, seemed to deteriorate much less rapidly than the usual careless juvenile diabetic. One of these patients gave little heed to diet for seven years, was thirsty, and had a blood sugar of nearly 0.3 per cent. when tested, and yet became rapidly controlled on diet without insulin, and has remained so since. Another, a girl of 12, had diabetes for seven years without any marked progression, and always responded at once to dietetic treatment. It seems possible that the low leak point acted in these cases as a safety valve, which tended, by the loss of sugar in the urine, to lower the blood sugar and relieve the strain on the islet cells. This is my impression in these two cases, but, of course, they may have been exceptionally unprogressive for other reasons.

It would appear that these cases respond to treatment in the usual way, but they certainly present some difficulty in their management. It is impossible to keep the urine sugar-free if the threshold is below 0.1 per cent. The usual urine sugar tests give little or no indication of the patient's real condition, which can be known by blood sugar tests alone, difficult to carry out frequently, and sometimes impossible. It is very disappointing to the patient, and the practitioner, to find sugar almost constantly present in spite of treatment, and the patient, at least, is apt to be depressed. It is best for these patients not to be taught to test their urine or to co-operate as much as usual in their treatment. If the threshold is lowered to only 0.14 per cent. or so, this may be almost an advantage in treatment, as one may then be certain, if the urine is sugar-free, that the blood sugar is normal.

It is difficult to see any etiological connexion between the lowered threshold and diabetes in these cases. It is highly improbable that the diabetes produces in some way a lowering of the threshold, for any change that is known to take place in diabetes is in the direction of a rise in the threshold; nor is there any clear evidence that a pre-existing condition of renal glycosuria may tend to produce or be followed by true diabetes. Indeed, Hjärne[4] has recently published a hereditary study of renal glycosuria which tends to show the absence of any connexion between diabetes mellitus and renal glycosuria.

The most likely explanation of these cases is the fortuitous development of true diabetes in cases of renal glycosuria. It is now well known that a lowered threshold is fairly common in normal individuals, though what percentage of the population are renal glycosuries it is impossible even to guess; but the number of cases of renal glycosuria that are discovered must be very small compared to the number existing. The above eight cases have occurred among some 500 diabetics—an incidence of 1.6 per cent., not a high one, probably no higher than in the non-diabetic population. Quite likely among my 500 diabetic cases others with a lowered threshold have escaped discovery, because it requires close observation and not infrequent blood sugar tests (not possible in every case) to establish the condition. There seems no reason to think that the combination of diabetes mellitus with a lowered renal threshold is not a mere coincidence.

VOMITING IN INFANCY.

BY

T. M. LING, M.A., B.M., B.CH.OXF.,

JOHN AND TEMPLE RESEARCH FELLOW IN DISEASES OF CHILDREN, ST. THOMAS'S HOSPITAL.

VOMITING is a very common presenting symptom during the first few months of life, and one about which the mother is not unnaturally anxious, as it signifies to her that her child is not getting sufficient nourishment.

In the act of vomiting the walls of the stomach contract, the diaphragm is pushed downwards in the full expiratory position, while powerful contractions of the abdominal muscles take place; at the same time the cardiac sphincter is relaxed and the gastric contents are expelled, chiefly as the result of the pressure exerted in the abdomen by the diaphragm and the abdominal muscles, aided to some extent by reversed peristalsis. As a general rule the pyloric sphincter is closed, but in some cases it may become relaxed, with the result that bile and intestinal contents are expelled with the vomit. The simplest method of bringing this mechanism into play is to overfill the stomach, especially if this is done rapidly before the walls of the stomach have time to adapt themselves to the sudden increase of gastric contents. Thus it is extremely common for breast-fed babies to vomit a small amount at the end of their feeds. Provided the gain in weight is within normal limits no treatment is required, and the symptoms may be regarded as one of Nature's "safety valves." If, however, it is found that the baby is gaining weight excessively, a little water should be given beforehand and the actual length of time spent over each feed decreased.

Vomiting from Birth.

All cases in which such a history is given should be regarded seriously, as a congenital obstruction of the duodenum is a possible cause. It is also important to realize that the symptoms of congenital pyloric obstruction may date from birth. As a general rule the vomit in the former is bile-stained, and jaundice may occur, but the distinction between the two conditions is really only of academic interest, as surgical intervention is indicated in both.

Various congenital malformations of the oesophagus that produce intractable regurgitation of food dating from birth are occasionally encountered. Some form of fusion of trachea and oesophagus is the most common deformity, and screening with the *x* rays may sometimes show conclusive evidence of obstruction. Treatment is of no avail.

Vomiting with an Acute Onset.

The sudden onset of vomiting, associated with diarrhoea, in an apparently healthy baby suggests immediately the possibility of an infection, of which the most likely site is the gastro-intestinal tract, particularly in artificially fed children. It is important, however, to realize that parenteral infections may produce exactly similar symptoms; the most common of these are pyelitis, bronchitis, and otitis media. Recent work, both in this country and in America, has drawn attention to the great frequency of acute pyelitis in babies, and unless the urine is examined the condition is frequently missed. In severe cases the onset is sudden, with marked fever, vomiting, diarrhoea, and convulsions or rigors: the latter are uncommon in children, and should always suggest an acute kidney infection. Other cases have a more insidious onset, with vomiting and persistent loss of weight as the outstanding features. It is essential in

any suspicious case to obtain a specimen of urine, which may be done most easily by placing the child on a mackintosh sheet and securing the urine that collects at the most dependent part. If the case is one of pyelitis the urine will be definitely turbid, and will show pus cells and motile bacilli under the microscope. The vast majority of such cases are due to infection with *B. coli*, and the essential part of the treatment is to administer large doses of alkali; 10 grains of potassium citrate and of sodium bicarbonate can be given with safety every three hours to a child of 6 months. The best criterion of the progress of the treatment is the reaction of the urine, and it is advisable to provide the mother with litmus paper and instructions to continue giving the medicine at frequent intervals till the urine is alkaline.

Acute infections of the middle ear are very common in children of all ages, and here again the usual presenting symptoms are screaming, vomiting, and sometimes diarrhœa; unless the drums are inspected in any suspicious case the first indication of local trouble will be the presence of a discharge.

Naturally the gastro-intestinal tract will require treatment irrespective as to whether it is the primary site of infection or not. A preliminary dose of castor oil—a drachm for a baby of 6 months—is advisable when the case is seen early, but is actually harmful in the later stages. A period of starvation of about eight to twelve hours' duration should follow, during which saline is given freely. If vomiting is marked a preliminary stomach wash is indicated, and later, food in small quantities. Boiled breast milk is ideal, but in its absence a half-strength dried milk mixture with a low sugar and fat content may be used.

The vomiting of acute intussusception is nearly always characteristic and the clinical picture of the condition distinctive. Emphasis should perhaps be laid on the suddenness of the onset and the periodicity of the pain; thus the mother may describe exactly the time of onset, and the baby itself will usually lie quite quiet between the attacks of pain and screaming. A rectal examination is especially important in diagnosing an early case, as the presence of blood may be detected in this way some time before it becomes visible on the napkin.

Vomiting with a Chronic Onset.

Very frequently the mother will complain that vomiting occurs shortly after each breast feed and is accompanied by prolonged screaming, the latter being especially marked at night. Such a history suggests a diagnosis of underfeeding. In breast-fed babies, whenever the question of the quantity of food is in doubt, test feeds are called for. These can be carried out with great ease in any intelligent household provided fairly accurate scales are available, and the determination of the weights before and after every feed during twenty-four hours climinates the need for calculations. Only on this principle is it possible to treat feeding difficulties with any measure of success; any other way involves guesswork. As a simple working rule it should be remembered that a child requires about 2½ ounces of breast milk per pound body weight per day, and if test feeds are carried out it is a simple matter to adapt the diet accordingly.

Vomiting *per se* may indicate overfeeding or underfeeding; in the former case it is due to the rejection of surplus food by an overfilled stomach, and in the latter to the regurgitation of air swallowed to compensate for the inadequate quantity of milk. The weight chart is naturally of great help in such cases, and test feeds will decide the extent of the discrepancy.

Congenital Pyloric Stenosis.

Vomiting is undoubtedly the predominant symptom of this condition, and in many cases the details provided by the mother make the diagnosis almost a certainty. The symptoms usually start at about the third week of life, and become progressively more severe and more characteristic. The child snatches at the breast or bottle for a few minutes and then vomits very forcibly, so that the food is ejected well beyond the cot. The motions are small and hard, and the child loses weight steadily. In making a diagnosis it is absolutely essential to watch the child being fed, as gastric peristalsis can be seen in an early case only during an attack of vomiting. The detection of the tumour is largely a matter of patience; it is important that the abdominal wall should be well relaxed, and this condition is most easily secured when the child is asleep; in difficu cases the examining fingers should be worked up und the liver margin as the tumour may be quite high up the abdomen.

It is now generally agreed that Rammstedt's operation is the correct treatment for this condition, but before it is actually undertaken attention should be paid to the following points, upon which depends very largely the success or otherwise of the operation.

1. Re-establishment of breast-feeding. Very frequently the persistent vomiting and loss of weight have been taken as indications that breast milk does not "agree" with the baby, and by the time the child is seen weaning may have occurred and perhaps two or three artificial foods tried without success. In many cases it is possible partially to re-establish breast secretion, and this should be done by putting the child to the breast regularly, and by breast massage. It will usually be necessary to give some artificial food in addition, but this should only be done after the baby has been put to the breast. Even small quantities of breast milk are invaluable for the feeds immediately following an operation.

2. Daily stomach washes should be instituted as soon as the diagnosis has been made, and it is surprising how much improvement may be brought about in the clinical condition of the baby in two or three days. A solution of sodium bicarbonate (a teaspoonful to the pint) should be used and the proceduro carried out about two hours after a feed; incidentally the amount of residue is a measure of the degree of stenosis and of the urgency for operation.

3. Subcutaneous saline should always be given immediately before operation, and, if the baby is at all wasted, it should be started as soon as the diagnosis is made and given regularly twice a day for two or three days.

From the above considerations it can be seen that it is advisable in the majority of cases to wait three or four days before undertaking operation so as to improve the general condition of the baby by medical means.

Habitual Vomiting.

From time to time cases are seen in which no dietetic error or organic disease can be found to account for the persistent vomiting that occurs usually just after a meal. There is frequently a neuropathic family history in such cases, and the baby itself is very restless, and cries at the least noise or distraction. It should be noted that some degree of peristalsis may be seen in these patients, although no pyloric tumour is palpable, and the progress of the condition will negative the latter diagnosis. By far the best treatment for such a condition is to thicken the feed with flour or fino oatmeal. In an ordinary case about half an ounce of flour may be added to a pint of milk mixture and the whole brought to the boil and allowed to simmer for ten minutes. The resultant mixture will be a thin gruel that will flow through a large hole in a teat. In pronounced cases that do not respond to this treatment it is necessary to use a thick cereal food that has the consistency of treaclo. Such a food may be made by allowing about 2 ounces of flour to each pint of milk and boiling the mixture gently for at least half an hour. From 2 t 4 ounces may be given at each feed, though naturally will be necessary to supply the requisite amount of flu by giving drinks of water between the feeds.

Some help may be obtained in cases of habitual vomiti by the use of a chin strap applied immediately after a feed, and from the administration of small doses of atropine and bromide. A convenient mixture is:

Solution of atropine sulphate (1 in 1,000)	...	2 minims
Sodium bromido	to	1 grain
Chloroform water	to	1 drachm

This should be given about half an hour before the feeds. As a general rule, however, it will be found that adequate thickening of the feeds is the essential part of the treatment, and the rapid improvement that ensues in the condition of the child is the surest proof of this.

THE OXIDASE REACTION IN THE LABORATORY DIAGNOSIS OF GONORRHOEA.

BY

I. N. ORPWOOD PRICE, D.P.H.,

ASSISTANT PATHOLOGIST, VENEREAL DISEASE DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE oxidase reaction is due to the presence of oxidizing ferments in certain organisms, and is characterized by a colour reaction produced when a reagent, such as dimethyl-para-phenylene-diamine hydrochloride, is poured on to the colonies of these organisms. The reaction is not specific for any organism, but is given, amongst others, by *B. anthracis*, *B. pyocyaneus*, *B. subtilis*, *B. choleræ*, and the Neisserian group.

Dietrich and Liebermeister[1] in 1902, whilst studying the detailed structure of the anthrax bacillus, made use of the oxidizing ferments present. In 1910 Schultze published a paper[2] on methods of observing oxidation and reduction in bacteria, and noted the organisms giving rise to this oxidase reaction. Kramer[3] in 1912 confirmed this work. Little further progress was made until 1928, when Gordon and McLeod published a paper[4] confirming most of Schultze's work, but they modified the latter's method so that it could be used as a means of differential diagnosis in mixed cultures and not be limited to pure subcultures. Their method was used throughout the present investigation, and consists in pouring on to the colonies of the organisms either phenylene-diamine hydrochloride or dimethyl-para-phenylene-diamine hydrochloride. Those colonies containing the oxidizing ferments present a colour change, whilst those that do not, remain unaffected.

The objective of the present investigation was to ascertain the value of this method in the routine examination for the presence of the gonococcus in cultures taken from the genital tract of patients who, clinically, had, or were suspected of having, gonorrhoea. The inoculation was made on to a modification of Thomson's medium (*p*H 7.5), as it became evident that the colour change shows up much more readily on this transparent medium than on the opaque brownish-red surface of blood agar. The test was applied after forty-eight hours' incubation at 37° C., the reagent used being a 1 per cent. solution of dimethyl-para-phenylene-diamine hydrochloride (supplied by the British Drug Houses) in distilled water. The solution should not be over seven days old, since with older solutions the colour reaction is less well defined.

The colonies were first examined with a ×6 hand lens, and samples of any having the appearance of being gonococci were picked off, stained by Jensen's modification of Gram's stain, and examined microscopically. If the organisms had the morphological appearances of gonococci this was noted. The surface of the medium was very gently washed with about 0.5 c.cm. of the reagent, thus avoiding contamination of colonies of gonococci by other organisms from other colonies. This is important when pure subcultures are required for vaccines, etc. The cultures were then observed by the naked eye and with a ×6 lens at intervals of 1, 3, 5, 10, 15, 20, and 30 minutes, and any colour change in a colony carefully noted. The results were recorded as positive, "pseudo," and negative reactions.

A positive reaction is shown by the development, almost immediately, of a very faint fine pink, which at this stage is only to be seen with the aid of a ×6 lens. In three minutes this deepens to a cerise shade, and the colonies are easily seen by the naked eye amongst those which are unaffected. Gradually the colour changes to red and then to reddish purple, finally ending, in about thirty minutes, in an intense jet black. This may be regarded as a normal reaction, but variations in the speed of the reaction do occur. They appear to depend on the age of the culture and the reagent; the older these are, the quicker, but less well defined, the reaction, whilst, within limits, the converse holds good.

The term "pseudo-reaction" was applied to a change of colour which was distinguishable from that seen in the truly positive reaction by being brownish pink rather than pure pink, and becoming in the end brownish black instead of jet black. It was afforded by some non-gonococcal colonies. A negative reaction indicates no change in a colony.

Two thousand cultures were examined, the first 250 of which were selected as a "trial run." These contained obvious gonococci colonies, doubtful gonococci colonies, and cultures obviously not containing any gonococci. The following 1,750 were routine cultures sent into the laboratory for examination. Of these 1,750 cultures there were 117 (6.7 per cent.) positive reactions, and all of these were morphologically gonococci. Many of these organisms were cultured and gave the typical glucose fermentation, other sugars, such as maltose, saccharose, levulose, etc., being unaffected. They were also soluble in caustic soda.

Other members of the Neisserian group also gave positive reactions, but the only one likely to confuse the issue in a case of doubtful gonorrhoea is the *M. catarrhalis*, and most authorities[5] are agreed that its presence in the genital tract is rare. The intensity and celerity of the reaction given by a few of the members of this group appear to depend on their ability to ferment the sugars. Thus, *M. catarrhalis* gives an extremely quick and vivid colour reaction, whilst *M. flavus* (Type 1 only tested) gives a slow response. Between these two extremes comes the gonococcus.

The "pseudo"-reactions (2.2 per cent.) were almost invariably given by one of the protean varieties of coliform bacilli. Gordon and McLeod report negative reactions with *B. coli*, whilst Schultze and Kramer found that it gave a definite response. From this investigation it would appear that some varieties of coliform bacilli give an oxidase reaction, but that the great majority remain unaffected. *B. subtilis*, when present, always gave a response, and in two instances this was noted with a variety of streptothrix.

Amongst the mixed cultures which gave negative oxidase reactions (91.1 per cent.) the gonococcus was not encountered, but on four occasions a very small Gram-negative coccus was noted, which it was possible to isolate in a pure culture on only one occasion, and then with great difficulty. It had the following characteristics: (1) Gram-negative, about one-quarter the size of the gonococcus, not arranged in pairs, and giving a negative oxidase reaction; (2) ferments glucose, lactose, maltose, and mannite with the production of acid but no gas; (3) no action on inulin or dulcite; (4) clots milk; (5) very poor growth on agar, but somewhat better on hydrocele agar, producing pin-point colonies, which were dull and sticky and required frequent subculture (every two or three days) in order to keep the strain alive. This organism appears to belong to the Neisserian group in spite of its negative oxidase reaction.

From these results it is evident that this method of diagnosis of the presence of gonococci colonies in a culture tube tends to increase accuracy, particularly in cultures where the colonies of gonococci have grown feebly or have been almost smothered by the growth of such secondary organisms as *B. coli* or staphylococci. A *definite* positive reaction removes the necessity of staining, whilst colonies giving doubtful results can always be stained and subcultured provided this is done prior to the colony assuming a blackish hue. When this occurs it is an indication that the organisms have been killed. Pseudo-reactions practically never give rise to any doubt except in cases where the reagent is not fresh or the cultures have been incubated for more than forty-eight hours. The strepto-pneumococcal colonies, which are so frequently a cause of anxiety owing to the similarity of their appearance to those of the gonococcus, never give a positive reaction, hence this potential error is removed. Finally, where large numbers of cultures are examined by this method there is a great saving of time and labour.

I would like to express my thanks to Dr. T. E. Osmond, pathologist to the venereal disease department, St. Thomas's Hospital, for his kind advice and assistance in the preparation of this paper, and also to Colonel L. W. Harrison, D.S.O., for permission to publish the same.

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

EPITHELIOMA OF THE SKIN IN A FEMALE COTTON OPERATIVE.

THE undermentioned case is considered worthy of record in view of the interest manifested in occupational carcinoma.

The patient, aged 66 years, was first seen in February, 1928, complaining of a growth on the right forearm which had been present about twelve months. She was of poor general condition and wasted musculature; general senile changes were present in all systems. A careful examination of the skin as a whole showed a mild xeroderma, but not of more marked degree than is often found in elderly persons of thin build. There was a pronounced diminution of subcutaneous fat, and considerable loss of elasticity. On lifting the skin between the forefinger and thumb there was a "tissue paper" wrinkling, such as is seen in a syphilitic scar—to the touch the skin imparted a sensation of dry parchment. Over the surface of the entire body, and to a far greater extent over the skin of the arms and neck, there were a number of islands of pigmentation, varying in depth of tint from a light brown to black. The size of these areas was equally variable, some patches being as much as half an inch across and others only pin-point. The changes described, however, were almost entirely confined to the lower two-thirds of the arm, the face, and the neck, although similar changes were to be seen in a very mild degree elsewhere on the body. Exposure of the skin, from lack of protection of clothing, appeared to have increased the tendency of the skin to these changes.

In addition to the areas of altered pigmentation there were multiple points of pigmented follicular hyperkeratosis and verrucae. Most of these were elevated above the skin to a conical formation 1/8 to 1/4 inch in depth and diameter. On the right forearm in its middle third a warty squamous-celled carcinoma was present; around this was considerable infiltration, due in part to secondary infection of the central lesion. There was no involvement of lymphatic glands, and excision of the growth and about an inch of surrounding skin gave an uninterrupted recovery. Examined later there was no sign of recurrence. Microscopical examination of the growth confirmed the diagnosis of epithelioma. The woman had been employed throughout the greater part of her working life in a carding-room of a cotton mill, and as such had been exposed to the effect of various mineral oils.

The condition is of interest in the possible association of the lesions with occupation. Similar skin lesions have been found in persons who have never been exposed to irritant oils, and it should perhaps be regarded as *post hoc* rather than *propter hoc*. A baker who develops eczema is not necessarily suffering from "bakers' itch."

A. H. SOUTHAM, M.D., M.Ch., F.R.C.S.
Manchester. P. B. MUMFORD, M.D., M.R.C.P.

IDIOSYNCRASY TO QUININE INJECTIONS.

DR. CRUIKSHANK'S memorandum (January 19th, p. 104) is an almost exact description of an experience of mine.

Mrs. X, aged 58, was referred to me by Dr. Whittington, honorary physician to Hove Hospital, suffering from varicose veins in both legs and with an eczematous spot below the left internal malleolus and a small painful ulcer. I injected 1 c.cm. of Douthwaite' solution into a vein in the left leg, and after mpress assisted her down without any difficulty from the chair on which she was standing. A few minutes later, while seated and putting on her stocking, she suddenly complained of a hot stifling sensation in her throat and a headache, and turned deathly white. I gave her some brandy and put her head down between her knees, but she became cyanosed, quite pulseless, pupils widely dilated, bladder sphincter relaxed, and she had a "rattle" in her throat. She was at once laid on the floor while camphor was administered subcutaneously and oxygen given. In a few minutes she regained consciousness and vomited, but her pulse still remained imperceptible at the wrist and no heart sounds could be heard with the stethoscope and her pupils were still dilated. She was placed on a couch and covered with blankets, given a drink of hot tea, and hot-water bottles were placed near her. She complained of feeling cold, having a splitting headache, and a sense of constriction in her throat. These symptoms gradually wore off, and in a couple of hours she was sufficiently recovered to be taken home by her daughter. Consciousness was only lost for a very short period, and the patient related to me minutely all that we had done from the moment she was laid on the floor. In a few days she was none the worse for her adventure, and her eczema and ulcer had almost disappeared.

I have twice before seen a similar occurrence; the first time was when a woman fell dead on my shoulder in an omnibus (the *post-mortem* examination showed atheroma of the coronary artery), and the second was when a patient of mine had an attack of angina pectoris in my presence and I thought he was dead, but camphor and oxygen were handy and he pulled round.

Mrs. X has a negative Wassermann reaction and a blood pressure of 150 (systolic); heart and lungs normal. On reading Dr. Cruikshank's memorandum I wrote a post-card inviting her to come to the out-patient department, and Dr. Whittington and I performed the dermal test as suggested, using my own forearm as a control. She showed a marked wheal surrounded by a zone of erythema, but only slight redness at the site of the distilled water control. On my own forearm no reaction was obtained to quinine.

This is the only case out of over a hundred treated by me with quinine injections in which alarming symptoms have occurred. However, I shall in future apply this very simple dermal test to all newcomers who cannot assure me of their ability to take quinine without ill effects, and I should advise others to do the same.

Hove. ST. GEORGE B. DELISLE GRAY.

THE TRANSMISSIBILITY OF PYORRHOEA ALVEOLARIS.

PYORRHOEA alveolaris is a complaint so widespread in its incidence and so destructive in its consequences that the investigation of its etiology is called for.

It is commonly stated that the condition originates in an accumulation of decomposing foodstuffs in the interstices of teeth, bacterial invasion and putrefaction of the debris being the starting point of a gingivitis which leads to periodontal inflammation. There is no doubt that inattention to dental hygiene and the consumption of soft foodstuffs, particularly confectionery, are frequently found among patients who bear evidence of this disease.

Observation of its onset among patients met in the ordinary run of general practice leads one to the conclusion that there are other predisposing factors which are equally if not more important; among these may be mentioned the following:

1. *Debilitating conditions.* After an attack of influenza it is common to note that the gums are spongy, while the patient complains that they bleed easily on being brushed. The condition may clear up entirely when the patient is restored to health.

2. *Alteration in the salivary reaction.* This occurs in general diseases, such as Addison's anaemia; in mouth breathers, particularly those who have suffered from long-standing nasal obstruction; and in heavy smokers where an excess of alkaline saliva constantly bathes the teeth.

3. *Direct infection.* This is probably more frequent than has been generally realized. Attention was drawn to the possibility of pyorrhoea being a contagious complaint by the following sequence of events.

A man, aged 35, with well-marked pyorrhoea affecting the lower incisors (the common site of invasion), was married to a young woman whose mouth was perfectly clean and the gums coralline. Two months after marriage the wife came for treatment of headache, and upon routine examination it was found that the gums were of a dull purplish hue and spongy in consistence. In spite of careful hygienic measures the condition spread until the majority of the teeth in the lower jaw became loosened and easily movable. The condition only showed signs of improvement when circumstances led her to visit her mother for a period of six weeks; upon her return to her home the gums were of firmer consistence, pink in colour, and no longer exuded pus on pressure. Since then her husband has had his offending teeth extracted and the wife's cure persists.

Taking heed from this object lesson, many cases have been watched, and in a considerable proportion it has been noted that the onset of pyorrhoea in young persons has dated from their first love affair. It has long been traditional that women lose teeth in every pregnancy, ascribed to the abstraction of calcium salts for the benefit of the uterine parasite. In the country these women are commonly sufferers from pyorrhoea, and it would appear to be reasonable to investigate the condition of their husbands' mouths before embarking upon treatment. It is an axiom that sweeping assertions should not be based upon evidence derived from a few cases in one man's practice, but it would appear that the possibility of transmission of pyorrhoea by direct contact might well be worked out by experts more fully equipped for dental research.

Sherborne. JOHN WHITTINGDALE, M.B., F.R.C.S.

METASTASES IN MAMMARY CARCINOMA.

THE unusual distribution of metastases in the following case seems to make it worthy of record.

A married woman, aged 39, consulted me in February about a nodule she had noticed in the upper and outer quadrant of her right breast. This was about the size of a walnut, apparently freely movable, and without any enlargement of the axillary glands on that side. A simple tumour was diagnosed, and I removed it with a good deal of the surrounding tissue.

Dr. W. H. Grace, pathologist to the Chester Royal Infirmary, reported on the specimen as follows: "This tissue shows the histological characteristics of a scirrhous carcinoma of the breast. There is a good deal of fibrous tissue, and a small amount of inflammatory reaction. The neoplastic process seems to be growing fairly rapidly."

The patient was then sent to the David Lewis Northern Hospital, Liverpool, where a radical operation was performed; from this she made a good recovery. She came to me again in September with what seemed to be an acute septic condition at the nail fold of the left middle finger. The nail was removed and the finger incised. One or two sloughs separated in a few days, but the purulent discharge continued for an unusually long time, and there seemed to be a very excessive amount of granulation tissue. When she returned from a short holiday at the end of October the tip of the finger was so large that a general anaesthetic was administered and the finger-tip reduced to a more normal size by cutting away most of the "*granulations.*"

Dr. Grace's report on these was as follows: "This is undoubtedly a secondary deposit of a carcinoma. The cells are arranged in such a way that it could be a reproduction of a carcinoma of the breast; the cells are taking up a certain amount of alveolar formation."

At this time there was no sign of any recurrence in the breast, axilla, or anywhere else. A few days later, however, she complained of severe headache round about what looked like a suppurating wen in the right parietal region. This turned out to be a hard, solid, and not very vascular mass, moving freely with the scalp, and certainly not a wen. Since then she has had almost continuous headache, with intermittent attacks of vomiting. On ordinary clinical examination neither the thorax nor the abdomen shows any abnormality, and there is no alteration in the reflexes.

Crewe. F. T. INGRAM, M.D.

Reports of Societies.

STARVATION IN TREATMENT.

At a meeting of the Medical Society of London on January 28th, with Dr. J. WALTER CARR, the president, in the chair, a discussion was held on "Starvation in treatment."

Dr. E. I. SPRIGGS opened by remarking that starvation was the common fate of a large number of living organisms; the human race in the course of ages had acquired a marvellous power of meeting this risk by the preparation, storage, and transportation of food. Fifteen years ago one might have been justified in thinking that starvation on a community scale was by way of being banished from human experience; since then there had been seen a gigantic experiment involving the partial starvation of millions of people. Experiments of this kind had been made many times before, but never on such dimensions, and not at all since nutrition had been placed on a scientific basis. In normal times, however, the ordinary man stood in much more danger of overfeeding than of underfeeding; therefore the withdrawal of the whole or part of the food was a rational and useful measure in many diseases. Starvation might be complete or partial: in the former case the predominant symptom was hunger, which was not quite the same thing as appetite. Indeed, probably most persons in an ordinary company had never at any time in their lives felt what hunger was. Discomfort arose in the neighbourhood of the epigastrium, which was insistent but intermittent, beginning, not at the moment when the stomach was empty, but some time afterwards. The modern view was that hunger pain was due to stomach contraction. The physiological data of starvation experiments had been worked out upon a number of people. It must be understood that when food was withheld the body did not starve; it went on feeding as long as it lived, but on its stores instead of on ingested material. The weight diminished rapidly at first, and then settled down to a loss of about one pound a day. If a man living a sedentary life, and expending 2,400 calories a day, cut off his food, his body endeavoured to bring down the expenditure to about 1,800 calories. The body exercised a great power of internal economy when fasting. The end came when mobilization failed, when the body stores were not supplied sufficiently to some important organ, though fat might still remain in the body. During fasting the blood pressure fell steadily as a rule. In some Continental observations on prisoners of war who were hunger-striking it was stated that the blood pressure in one case dropped as low as 55 systolic. The temperature did not drop during fasting, or dropped very little. The mental state in a moderate fast was not, so far as could be ascertained, affected, but if fasting was prolonged curious mental states might develop. The loss of weight, apart from the fat, fell first of all on the glands. The liver, spleen, and pancreas lost more than any parts of the body, the muscles came next, and the heart and brain last. When food was stopped the first call was upon the glycogen of the liver, and after this upon the more mobile stores of protein; next on the so-called deposit protein; and last on the tissue protein. The fat was, of course, the main source of energy during fasting; owing to *the large amount of fat being burned its metabolism* was liable to be incomplete, with the production of acidosis. The benefit which fasting had been found to confer on epileptics was ascribed to the acidosis produced, which combated the alkalosis associated with that condition. The blood sugar remained constant until death was approaching; no doubt the sugar was derived from protein and probably fat. There was a general idea that fasting cleared the blood: in fact the nitrogen content of the blood altered very little, and any change was in the direction of concentration. There was nearly always more *uric acid in the blood of the* fasting person; the calcium was also rather increased. The blood in fasting was like a highway filled with traffic on an emergency mobilization; it was not purified in fasting, but rather the reverse; the organs that were purified were the glandular organs. As regards the secretions, that of hydrochloric acid generally ceased; milk secretion went on for a few days and then stopped. Fasting had no known specific effect on the healthy body except to call into being its whole resistance against the risk of approaching death. Turning again to the war experiment, Dr. Spriggs said that it had confirmed the scientific work of the previous generation as to body needs. The stress on the population in many parts of Germany was very severe; it was said that there was not a poor man in Berlin who weighed more than 8 stone. The restricted diet resulted at first in an improvement of health, but nervous symptoms presently appeared, and afterwards anaemia, myxoedema, and digestive diseases were widely current. Coming to the employment of starvation in disease, the speaker said that complete starvation had been used for local disease of the alimentary canal; in acute diseases such as appendicitis it was a temporary measure. It was not advisable to continue complete starvation for any long time; men might survive it and say they felt better, but it was a feat of endurance and nothing more. Short complete fasts had proved beneficial—no food, but plenty of water or other fluid—*for one, two, or three* days. Growths were benefited, particularly those of the muscles and connective tissue; a great many skin diseases also responded to fasting, and rheumatic conditions were reported as benefited. In acute nephritis and other acute illnesses it was a common thing to cut off food. Dr. Spriggs then related experiences with his own patients in obesity, and recounted consistent results. Diminution of food was the one certain means of treating this condition; those other physical treatments to which patients attached so much importance, such as massage and baths, did nothing to diminish weight. The method he employed was to give a measured mixed diet containing sufficient protein for the bodily needs. He exhibited dietary tables for successive days, each day with four meals and a plentiful variety of food at each, but designed with due regard to the individual case so as to diminish gradually the calorie value by about 100 calories a day. If hunger was felt the patient might be given a portion of cold lean meat and nothing else, or,

better still, a cup of bovril. The object of the method was to enable the patient to continue treatment, with the aid of his doctor, after the course was over, without risk. One-food cures were less desirable, for they could only be borne for a time, the patient then returning to his old habits. The value of reduced diets in plethora and diabetes was described. He concluded with some remarks about the cults of fasting, pointing out that all methods of treatment which did good were liable to abuse. He gave particulars of a trial at Göttingen in which a doctor was indicted for causing the death of a patient by negligence. The patient had been put on a fasting cure, and given only lemon squash and a teaspoonful daily of a vitamin preparation for six weeks. The defence was a curious document, in which death was ascribed, not to lack of food, but to persistence in hot baths against the doctor's advice. The court found the doctor guilty of submitting a healthy, or nearly healthy, man to a dangerous treatment, and fined him 300 gold marks, with the alternative of a month's imprisonment.

Dr. F. PARKES WEBER said that voluntary intermittent fasting was simply a return to the involuntary habits which dominated the lives of our primitive ancestors. Nature still to-day retained her own ascendancy by withdrawing the desire for food in most acute diseases or when, as the result of overfeeding, the digestive mechanism had been upset. An important aspect of therapeutic fasting was the use of intermittent absolute or relative fasts for ailments such as gout, diabetes mellitus, some forms of obesity, and some diseases and disorders of the digestive organs, including appendicitis. In some persons a limited diet had the effect of increasing the resistance against colds in the head or sore throats. He recalled how, as far back as 1909, he treated a case of diabetes mellitus by the temporary limitation of intake to water and olive oil for a short time, and the patient was rendered temporarily free from sugar. One noteworthy non-medical writer on the subject was Mark Twain, whose amusing skit on the "appetite cure" was meant to show how large a part a limitation in diet played in the treatment of ailments for which the fashionable world flocked to the healing springs. Mark Twain said that no cold in the head could survive twenty-four hours' unmodified starvation.

Dr. ANTHONY FEILING described a recent case where a fever terminated dramatically as a result of starvation diet. The man had been feverish, with a temperature of 103° in the evening, for a week before he came into hospital; it appeared to be a case of mild typhoid or paratyphoid infection. After some time he was put on complete starvation (except for water), and this was kept up for three days; then he was put on a diet of sour milk, one pint a day for a week. His temperature went down suddenly, showed no tendency again to rise, and he left the hospital perfectly well.

Dr. GRAHAM LITTLE spoke of the use of starvation in skin diseases, where sometimes the most amazing results were seen. A friend of his, a New York dermatologist, who himself suffered from a severe skin eruption, was able to control it by confining his diet for the time to rice, bread-and-butter, and water; he was able to live on that diet quite comfortably for a week or more without appreciably losing weight. Much more effective was what was known as the Welper method, which the speaker had used in his practice for eight years; this was a combination of fasting and purging. The patient was made to fast for thirty-six hours, having no food except perhaps orange juice, and was given a large dose of some aperient. He mentioned one distressing case of acute lichen planus, for which he prescribed two days' fasting, with a purge on the first day; the whole eruption vanished within a week. For securing a very rapid amelioration of symptoms where the cause could be traced to a bowel accumulation this was a very useful method.

Dr. H. A. DES VOEUX mentioned two kinds of cases in which he had been accustomed to use starvation treatment. One was in illness resulting from overfeeding in children of the well-to-do, and the other was in acute illness like acute pneumonia. He had put his pneumonia cases on water for the last twenty or twenty-five years, and there was nothing for which he received more gratitude from them for excluding that continual fussy "nourishment" at short intervals.

Dr. A. P. CAWADIAS thought it important to distinguish between the therapeutic period in a fast—a period lasting perhaps four or five days—and the subsequent toxic period, where the equilibrium of the individual had become imperfect, and any infection might bring about catastrophe. From the clinical point of view it was very important to terminate the regime before the toxic period began.

Dr. GEORGE GRAHAM suggested that the miserable feeling noted in starvation patients after a certain time was due to insufficient carbohydrates.

Dr. SPRIGGS, in reply, agreed with Dr. des Voeux on the treatment of acute pneumonia, though his own practice had been to give, not water, but fruit juice, a vehicle for the introduction of glucose, which was extremely useful to such people. In his original remarks he had spoken rather slightingly of single-food cures, but occasional days on one food were beneficial, and were used by him. A day on which nothing was taken but six Jaffa oranges, furnishing about 350 calories, might be a very good thing; also a milk day. He agreed with Dr. Graham that in cases of difficulty in starvation it was well to increase the carbohydrates; he had found it useful to give a meal of buttered toast to people complaining of headaches. On the whole subject, he thought it might be said that fasting was of great value in many conditions, but should always be undertaken under medical supervision.

CRIMINAL ABORTION AND THE SALE OF ABORTIFACIENT DRUGS.

A DEBATE on the question of criminal abortion and the measures necessary to restrict the sale of abortifacient drugs took place at a combined meeting of the Medico-Legal Society and the Child Welfare Group of the Society of Medical Officers of Health on January 23rd, with Sir WILLIAM WILLCOX in the chair.

Dr. F. J. MCCANN, in opening, said that abortion was undoubtedly increasing in this country. From so-called natural causes it was not uncommon—some gave the proportion of one in five or six full-time pregnancies—but it was probably not an overestimate to say that of the total number of abortions 25 per cent. were criminal. The figures, however, varied with locality. Another point to bear in mind was that some women aborted very easily, while others could be subjected to great violence, internally and externally, without abortion. Dr. McCann showed some anatomical sketches to illustrate the structures concerned, and indicated how serious might be the consequences of the passage of an instrument—sometimes even in skilled hands. It was remarkable how many kinds of instruments were used in abortion cases—skewers, button-hooks, pieces of twig, hairpins, bodkins, had been passed along the vagina. The question arose whether a woman could successfully procure abortion on herself. The answer was in the affirmative, though some women who said they had done it themselves were hiding the real culprit. The one thing that haunted the abortionist, skilled or unskilled, was shock, which could neither be foretold nor prevented. Some women suffered a great amount of shock when any interference took place, the reason being, he thought, that they went to the abortionist with *their* nerves already strung up to concert pitch, knowing themselves about to take a grave, possibly a fatal, risk. The character of the patient also led to the undoing of many abortionists. The patients as a rule were wilful and disobedient, and refused to stay in bed lest suspicion be aroused, although rest in bed was more necessary after an abortion artificially induced than after abortion from so-called natural causes. Dr. McCann then turned to the question of drugs, and mentioned some of the emmenagogues and ecbolics in common use. Some patients had told him that they had produced abortion with large doses of quinine, the action of quinine being intensified by castor oil. Savine, an irritant poison, was also used. In Vienna phosphorus was said to be largely employed. Diachylon or lead plaster, which had terrible effects, was another article of common

resort. The nefarious traffic in abortifacients was still going on, especially in shops in side streets, where drugs were advertised "to cure irregularities, suppressions, and obstructions." Everybody knew that if a healthy woman's menstrual periods ceased the cause in 999 cases out of 1,000 was pregnancy. These gentlemen had no justification whatever for their advertisements. It seemed to him that no alteration in the law was necessary. The Home Secretary and the police had only to act promptly and with courage and they could stop the whole thing at once. He suggested that the Home Secretary be asked to receive a deputation from the Medico-Legal Society and kindred bodies, and that a committee be formed of representatives of the Royal Colleges of Physicians of London and Edinburgh, the British Medical Association, and the Pharmaceutical Society, to inquire into and report upon all the proprietary drugs before they were exposed for sale, so that the composition of the drugs might be known, and also for what purpose they were intended.

Dr. R. A. LYSTER said that the law at the present time was satisfactory if energetically administered. Indeed, it dealt with abortion-mongering in a fairly drastic manner, the reason being that years ago, when the law was framed, a very serious view was taken of the moral aspect of the case and of the sanctity of the embryo. Later certain other important considerations had emerged—namely, that abortion was a very serious factor in infant mortality and maternal invalidity. A successful abortion very often meant a damaged woman; an unsuccessful abortion a damaged woman and a damaged child also. He imagined that the fatalities from abortions or attempted abortions were tending to decrease, thanks to a more general appreciation of asepsis, antisepsis, and after-care; the question was whether the damage resulting was tending to decrease as well. There was a fashion in abortions, and a recent number of sudden deaths from shock illustrated the fact that the modern fashion was by means of intrauterine injections. Had the public modified its view as to the criminality of abortion? Would the great mass of new women voters cast their influence in this direction? It would be rash to prophesy when so soon one might be discovered entirely wrong, but the position was well worth considering. Could the law be tightened up? Diachylon, or lead plaster, was put in Part I of the Poisons Schedule because its easy purchase was regarded as a public danger, but he doubted whether this had had any appreciable effect upon the general tide of abortion. Although lead was the surest abortifacient known to-day, difficulty in obtaining it simply switched people on to other means. A great deal of nonsense was talked and written about the action of certain things in producing abortion. A healthy normal uterus could only be induced to abort with very great difficulty, and all the alleged ecbolics might be given in vain. If the uterus was not inclined to abort all these drugs were useless. This was taken advantage of by abortion-mongers, who applied their methods as nearly as possible at a menstrual period when the uterus had an inclination to contract. The only certain abortifacient was a general poison, and the common general poison was lead. A woman who had taken lead successfully and produced abortion was a woman suffering from all the signs and symptoms of general lead poisoning, with one other—namely, contraction of the uterus, with expulsion of the embryo, commonly, not always, preceded by the death of the embryo, but invariably by serious damage to it. Abortion was a grave national danger in its effect on the physique of women and children, but a campaign embarked upon too precipitately without due regard to possible changes in public opinion might create more difficulties than it settled.

Sir BERNARD SPILSBURY spoke of the appalling frequency of abortion. A general practitioner, called to a case of miscarriage, could never be quite certain whether it was natural or had been procured. The estimate of 25 per cent. of all abortions as criminal was certainly not too high. Most of the serious cases of drug abortion which caused death had occurred in past years; in recent years the drugs used were not frequently drugs endangering life—many of them were drugs which one would be inclined to regard as comparatively harmless, and for some other purposes very useful. These drugs must often have been taken successfully by women who aborted readily, and thus they got a reputation. When abortion was induced eventually by instrumental means it was found almost invariably that previous unsuccessful resort had been made to drugs. The use of dangerous ecbolics seemed to be more or less restricted to those who had legitimate access to them—namely, doctors and chemists. Quinine just after the war was largely used for abortion; he saw two fatal cases about 1920, in which large doses had been taken. One of the most effective of the ecbolics, pituitary extract, fortunately did not lend itself to administration by the layman. With regard to general poisons, again, the number of cases of poisoning by drugs used to procure abortion had greatly diminished of recent years. He had not seen a fatal case of poisoning of this description since 1918, and now that diachylon was much more difficult to obtain, such cases had still further diminished. Mercury, phosphorus, and arsenic were only rarely used, and he thought they could be regarded as playing an unimportant part in the question. It was a very different story with the heterogeneous group of drugs so widely advertised for "female irregularities." The most important were the drastic purgatives, for which there was, no doubt, a big sale at the present time. Could legislation stop the sale of these drugs without interfering with their legitimate purpose? One feature of all the drug abortions was that the abortion was like a natural one, not liable to be followed by the dangers consequent upon the use of instruments, such as shock, loss of blood, and sepsis. That was why there was so little information as to how far drugs of this kind were used for the purpose. In addition to purgatives there was a whole host of other drugs offered, agents apparently possessing very small value. No drug, of course, could be accounted harmless if it had any reputation at all. Even pennyroyal and many patent medicines had been used, and it was stated that the desired results had followed. But he could not help feeling that with the present schedule of poisons there was such a restriction on the sale of dangerous drugs that the others could be left on one side in the hope that the public would soon be educated with regard to the unlawfulness of attempting to procure abortion by this or that means. There had no doubt been a change of opinion of recent years as to the criminality of abortion, and in the districts where the professional abortionist carried on his work he was exceedingly popular; he got the most dreadful results, but his popularity did not seem to wane. In spite of frequent fatalities and the announcement of them in the press, instrumental means were still being used very widely. On an average recently he made a *post-mortem* examination on a fatal case of abortion about every ten days; in the vast majority of cases these were criminal abortions, and, again in the vast majority, had been brought about by instrumental interference. It was to the education of the public in the wrongfulness and especially the danger of abortion that one must look for an improvement in the situation. The abortionist, skilled or unskilled, was a public menace. He knew that he went about in fear of prosecution, therefore he had to practise his calling with haste and secrecy, which meant that he had to operate under unsatisfactory conditions, and to run considerable risk of sepsis, so that even the skilled abortionist got most dire results.

Mr. BECKWITH WHITEHOUSE said that a great number of the abortifacients sold to-day were, fortunately for the woman, frauds imposed upon the credulity of the public. Again and again practitioners were faced with a request or a demand from a patient for medical treatment after she had been taking some proprietary preparation which had failed of its expected effect. What always amazed him was the moral attitude of the woman who set her mind upon the termination of her pregnancy. No argument or threat would turn her from her path. During the last six months he had been approached by five patients with a request, expressed or implied, to terminate their pregnancies; four of these were married women. Needless to say, there was nothing to justify operative intervention, and he refused. Two of the married women, however, induced another medical man on what he considered medical grounds to perform an operation. One of them developed pelvic

thrombosis, and had been in bed since August. Another induced abortion by injecting hot water into the uterus in the bath. She did herself much injury, and had a stormy convalescence. Among the poisons or noxious things principally used in the obstetrical underworld were lead, savine, aloes, pennyroyal, quinine, and occasionally, in his part of Worcestershire, tansy. Some years ago in Birmingham it was common to take lead, and cases of plumbism were frequent. It was to be hoped there would not be a revival for abortifacient purposes of lead in its colloidal form. As for instruments, a popular one was known as "slippery elm"—a piece of elm wood. The *British Medical Journal* in 1898 (ii, p. 749) mentioned the case of a woman who had introduced a thick knitting-needle into the uterus thirty-five times! An argument against the absolute prohibition of drugs, apart from the fact that some of the drugs used were of value for legitimate therapeutic purposes, was that such action was likely to be followed by a more extensive use of mechanical, and therefore more dangerous, methods, the comparatively safe and innocuous pill giving place to the septic and pointed crotchet-hook. One way of tackling the problem would be to call the attention of women to the risks to their future health and happiness which every operation, criminal or otherwise, involved. Recently he had been paying some attention to the corpus luteum. There was evidence that if pregnancy was suddenly and violently terminated while this structure was in full course of development a deleterious effect upon the corpus luteum was brought about which might be a factor in the production of lutean cyst. Abortion might have a more lasting effect upon the individual than was commonly suspected, and if this were made known it was possible that it would serve as a deterrent to criminal action.

Mr. H. D. ROOME (prosecuting counsel to the Crown) referred to the case of a clerical abortion-monger, the Rev. Francis Bacon (*British Medical Journal*, 1928, i, p. 329), whom he had prosecuted at the Central Criminal Court. This man conducted a mail order business in abortifacients. He had preparations labelled in increasing degrees of potency, and the most potent, consisting of a large quantity of quinine, aloes, and ergot, was recommended by him as an infallible cure for "female irregularities." In order to make a defence in advance he put on the mixture, "This preparation must on no account be taken by pregnant women." Mr. Roome agreed with a previous speaker that the law required no strengthening. The whole law regarding abortion was contained in two short sections of the Offences against the Person Act, 1861. The first of these sections made it a criminal offence for any person to use an instrument or any other means whatsoever, or to administer any poison or noxious thing with intent to procure the miscarriage of any woman, whether she be or be not with child. The penalty was penal servitude for life. The second section prohibited the supply or procuring by any person with a like intent of an instrument or anything whatsoever, or a poison or any noxious thing, and the penalty was five years' penal servitude. A "noxious thing" was regarded by the judges as any preparation administered in sufficient quantities to be likely to produce abortion; therefore a drug like quinine, on the face of it perfectly harmless, would, if administered in such quantities, bring the administrator within the statute. The ecbolics within the schedule of poisons included ergot, savine, arsenic, cantharides, tartar emetic, belladonna, and lead. Many reputed ecbolics and emmenagogues—the latter very often mere subterfuges for ecbolics—were supplied by persons who advertised themselves under women's names, holding themselves out as sympathizing with women in distress. The Rev. Francis Bacon headed his advertisements, "As woman to woman." In all these cases the law was drastic and sufficient. Something might be done by scheduling in the Pharmacy and Poisons Act any other preparation which in medical opinion was sufficiently dangerous to warrant it. The speaker himself believed that there was no infallible ecbolic, though even gamboge, hellebore, pennyroyal, or oil of juniper, if administered at a critical time, was extremely likely to bring about abortion, and something might be done if these were scheduled. The real cure was change of public opinion, and if there was more toleration and charity for the unmarried mother it would go a long way to stop one prolific cause of abortion.

Dr. G. ROCHE LYNCH (senior official analyst to the Home Office) agreed that the first resort of the woman who desired to terminate her pregnancy was to drugs. Many of the drugs sold to her had no abortifacient action whatever; they were simply frauds. He knew of one case where an unfortunate girl spent £40 on drugs which, on analysis, were shown to consist of iron salts, starch, garlic, sage, and clover. Of drugs of the more harmful type, far and away the commonest sent for analysis was the aloes pill, generally combined with iron. Others included quinine and some of the essential oils, such as pennyroyal and tansy, and occasionally savine. Very rarely one came across ergot, and lead had completely disappeared. To put lead itself in the Dangerous Drugs Act would be futile. There were cases on record of abortions induced by people taking a piece of old lead pipe, steeping it in vinegar for a week or two, and drinking the liquid. A great deal of this harmful traffic would be limited by preventing the selling of drugs of this class by anybody not a qualified chemist. As far back as 1914 there were some strong recommendations made about the trade in abortifacients, and it was said that the law was chaotic and had proved inoperative, but the sale of such drugs was in practically the same state to-day.

Miss SUSAN MUSSON (general secretary of the National Council for the Unmarried Mother) spoke of the large number of cases which came the way of her society in which drugs had been taken with a view to producing abortion. Very many of these girls had not the smallest idea that they were doing anything wrong. Among the abortifacients used, quite a common one in the East End was gunpowder taken in gin. Another very popular one was known as "hickery-pickery." (Sir WILLIAM WILLCOX said that this last was hiera-picra, a mixture of aloes and canella alba.)

Lord RIDDELL mentioned what had been done by concerted action on the part of the newspapers to stop advertisements of these drugs. As a result such advertisements were much less common than formerly.

Dr. NORMAN HAIRE said that as a well-known advocate of birth control he received as many applications to perform abortion as any practitioner in London. He always refused them, though he never pretended that he did so on moral grounds; he refused because it was criminal and against the law. But there was a considerable body of opinion amongst cultured people of high ethical standing that while abortion was a crime it was not necessarily a moral offence, and the question was how far that would come to be taken into consideration from the legal point of view. In Russia, under the Soviet, abortion up to three months' pregnancy was legal, and a similar law had been drafted in Czechoslovakia, while in Austria and Germany public opinion, especially medical opinion, was tending in the same direction.

Professor LOUISE MCILROY mentioned the great ethical difficulty created by the large number of cases which came to hospital following an induced abortion. It always seemed to her a pity that no method was available to the medical man or woman, seeing such cases and knowing the facts, of preventing further abortions. What should the attitude of the medical profession be, with due regard to professional secrecy, in such cases?

Sir WILLIAM WILLCOX, in closing the discussion, said that the opinion of a part of the medical profession with regard to this question appeared to have altered of recent years. At a discussion on the subject at the Royal Society of Medicine two years ago (*British Medical Journal*, 1927, i, p. 188) he was astounded at the opinions expressed by some members of the profession with regard to the moral aspect. They seemed to regard it as it was said to be regarded in Russia and Czechoslovakia. References had been made to the scheduling of abortifacient drugs. It was a difficult question, but probably the law relating to the sale of poisons would be completely altered and reformed in the near future. In the report of the Departmental Committee now in the stage of production it was not unlikely that great changes in the scheduling of poisons would be recommended.

VACCINATION IN THE LIGHT OF RECENT EXPERIENCE.

IN the Section of Epidemiology of the Royal Society of Medicine on January 24th, under the chairmanship of Dr. F. E. FREMANTLE, M.P., Professor J. C. G. LEDINGHAM opened a discussion on vaccination in the light of recent experience.

Professor Ledingham said that much of the new knowledge about the vaccination process, perhaps the most important part of it, had emerged from comparatively recent experimental research, not only on vaccinia and small-pox, but on virus diseases generally. The impression which recent work left on his mind was that in the process of accommodation of the small-pox virus to the rabbit or calf some element responsible for producing generalized lesions as distinct from general invasion was lost; this element might conceivably be another virus. There was good evidence that vaccinia afforded better protection against small-pox than small-pox did against vaccinia. What might be called the "attenuated virus" in the Jennerian or Pasteurian sense remained the most efficient immunizing agent. It was possible, however, that variola-vaccine of known recent origin might be still more effective than vaccinia as ordinarily propagated. There was no more pressing problem than that of the standardization of the immunizing powers of viruses, and especially of vaccine strains. Professor Ledingham regretted that the continued prevalence of mild small-pox in this country during the past seven or nine years had induced so few health authorities or physicians to furnish systematic accounts of it in all its bearings. He preferred the designation "alastrim" for this disease, because, so far as he had been able to contrast what records we had of it with those of the South American and South African types, he had failed to note any outstanding differences. While he used the word "alastrim" for convenience of nomenclature, he did not ignore the fact that the disease was a small-pox variant. Was it a fixed and stable variant or a mutant? In all probability it was stable. When it was alleged that case mortality had risen to a significant percentage in a country in which it had previously been well under unity in spite of thousands of cases, he thought it would be found that sufficient consideration had not been given to the possibility that the virulent form of small-pox had been somewhere incident alongside the alastrim, but without definite transitions. His reading of Rajchman's recent analysis of small-pox incidence and case mortality in many countries (*British Medical Journal*, 1928, ii, p. 521) would seem to justify the conclusion to which Rajchman arrived, that two entirely distinct types of small-pox prevailed which apparently bred true. The virulent form had a mortality rate which fluctuated, in long waves of six or seven years' duration, between 10 and 30 per cent. The mild type, on the other hand, had minimal figures ranging from 0.1 to 0.3 per cent. There was no evidence that minimal periods in case mortality of the virulent type were simply transitions towards an alastrim period with its negligible mortality. The result was important, and went at any rate some distance towards the controverting of arguments based on a reputed increase of case mortality rates in countries where alastrim was widely prevalent. The speaker next made a brief reference to post-vaccinal encephalitis. Much had been made of the constancy of the period after vaccination at which nervous symptoms commenced in such cases, but he took the view that the apparent constancy of this period might fit equally well with the theory which presupposed some latent neurotropic virus in the vaccinees to be activated by vaccinia. Fortunately these cases of post-vaccinal encephalitis were rare; practically all of them had been primary vaccinees, and the great bulk children of school age. The reason why a primary vaccination in infancy was apparently a protection against such accidents in later vaccinations might arise simply from the fact that in the allergic or accelerated reactions exhibited by partially immune subjects the virus was precluded from invading the system, and thus from inducing these nervous disturbances to which the subject might perhaps be liable if the vaccination were primary. He thought the extreme rarity of these cases ought not to be allowed to exercise any unwarrantable depreciatory effect on the practice of vaccination, but this new experience should have the effect of furthering infant vaccination and of inculcating perhaps greater circumspection and caution in the primary vaccination of older children and adults. Finally, Professor Ledingham indicated certain lines on which a discussion involving the practice of vaccination might usually run. Was the mild small-pox or alastrim worth preventing by vaccination? It was said that many persons would rather have alastrim than vaccination; nevertheless, a residuum of cases of alastrim were characterized by troublesome symptoms. If it was necessary only to consider the individual victim, who had, indeed, only himself to blame for his neglect, and he and his equally neglectful contacts took all responsibility, including financial, it might be expedient to "let the disease rip" and save the public purse. But the variola tradition would be likely to prevent the public health officer from acquiescing in this view. Variola had always been ranked with plague and cholera as the death-dealing diseases against which a civilized community must protect itself; consequently, though alastrim was practically harmless, all the expensive paraphernalia of small-pox control and hospitalization must be maintained. Vaccination and revaccination could "deliver the goods," and was cheaper. So why not consider vaccination afresh and not as a traditional century-old policy? How were the merits of vaccination to be spread abroad? No serious attempt had ever been made to explain to all and sundry what vaccination was and did. The man in the street could talk about the planetary systems of an atom, but he had little notion of vaccination except that it had something to do with sore arms and possibly a calf. Cheap and authoritative pamphlets were wanted as part of an educational crusade, but not designed after the cold-blooded manner of the income tax form. Further to recommend it, he suggested that in the light of the nervous sequels it might be expedient to reduce the dose to one insertion, especially for primary vaccination at school age, on the chance that there might be some correlation between the dose of vaccine virus and the degree of risk of some latent parasitism being stimulated to activity. The reduction to one insertion would also diminish the risk of septic troubles; but the procedure could only be fully justified if revaccination in similar fashion and at the time of leaving school was made a routine practice. Finally, he suggested that compulsory vaccination—such as it was, or was not, at the present time—might be abandoned for vaccination on a purely optional basis, and be introduced to the people at large with the accompaniment of a sympathetic and informative propaganda. By concentration on the education of the public as to the value of vaccination, and by removing what compulsory elements remained in the Vaccination Acts, he thought it possible that a very much larger total of voluntary vaccinations and revaccinations might be secured throughout the country.

Dr. C. KILLICK MILLARD (M.O.H., Leicester) was glad that Professor Ledingham had spoken so frankly about small-pox and alastrim being two separate entities; it was time this was officially recognized. He preferred to call the two conditions major and minor small-pox; they were closely related, of course, and the latter might be a stable variant or a mutant, but there was a fixed difference. He doubted whether in any outbreak there had ever been a question in the minds of those called upon to deal with it as to whether the major or the minor condition was involved. The present position from the statistical point of view was very unsatisfactory. The two things were lumped together in the same column without discrimination. What possible value would posterity attach to our small-pox statistics? He could not help thinking that the lumping together of these two things as a single entity had been largely under the influence of ulterior considerations. Professor Ledingham had referred to the variola tradition. There was such a thing as a vaccination tradition, in which medical men were, unfortunately, brought up, and which influenced their attitude throughout life. He took exception to the remark that vaccination and revaccination "delivered the goods." It sounded very clear and definite, and if the reference

was to the individual there was no question about its truth, but if the reference was to the community it was doubtful whether the statement could be justified. In what community had vaccination and revaccination effectually prevented small-pox and small-pox deaths? It was quite easy for laboratory epidemiologists to take a piece of paper and say that vaccination performed every five or ten years would immunize the individual, and that it followed that if all the individuals in the community were taken and vaccinated at certain periods the community would be protected. But in practice this could not be done. The attempt to do it in a country like ours had failed, and always would fail. When he first went to Leicester vaccination on wholesale lines was quite out of the question, but the isolation and prevention of contacts was readily available, and there had not been a single death from small-pox in Leicester for many years. Now that major small-pox had left the country, and what one had to deal with was a minor non-fatal small-pox, the whole attitude towards this question was ready for readjustment. What justification was there for attempting to force vaccination upon the community? It was a proposition which would never be accepted by the people of this country unless virulent small-pox came back in a form which could not be controlled.

Sir GEORGE BUCHANAN agreed with Professor Ledingham that the extent to which vaccination could be effectively recommended to the people of this country would depend upon the question of the safety of the procedure. It was true that the risks from vaccination were, relatively to the immense number of vaccinations which took place without the smallest mishap, of a very minor order indeed; but the point was that the small-pox experienced in this country of recent years was of so mild a type that the average parent would only assent to this precautionary measure if he was assured that it involved not the slightest risk. These possible risks should be investigated very fully, and every bit of new knowledge which tended to their removal should be worked out. This was not solely a British problem. The rare cases of post-vaccinal encephalitis had occurred in other countries, notably in Holland. On the Vaccination Commission it had been felt to be very important to ask administrators in various countries to do what they could to ascertain whether any chance cases of post-vaccinal encephalitis were occurring in their areas without their knowledge. Certain countries, especially the Scandinavian, had undertaken to make an extensive search and report the results.

Dr. MONCKTON COPEMAN believed that probably the first occurrence of alastrim in this country was at Cambridge in 1903. About that time he had a talk on the subject with the late Sir Clifford Allbutt, who, in reply to his (Dr. Copeman's) suggestion that he felt certain that this would turn out to be a variant of small-pox, said: "Well, if this is small-pox there is an end of all diagnosis!" At a later period Sir Clifford Allbutt made acknowledgement of Dr. Copeman's truthful prediction. The alastrim which occurred at this period was of a more severe type than in most of the recent outbreaks, the mortality was distinctly higher, and it was interesting to observe a considerable difference in the mortality rate as between the vaccinated and unvaccinated, showing that in alastrim vaccination had a considerable effect. In his mind there was no question that alastrim was a variant of small-pox, and not a separate disease. He thought it unfortunate that originally vaccination should have come under the administration of the Poor Law, which gave it a certain stigma, but in the future, with this service placed alongside other public health services, an improvement in public appreciation might be expected.

Dr. R. P. GARROW said that those in a position to make observations about the disease from personal observation—that is, medical officers of health—did not, as a rule, care to express views which were not quite orthodox. Official medicine liked always to look in the same direction. On the question of variants, he was of opinion that there were two diseases. He had been medical officer of health for eight years in a town (Chesterfield) where the mild disease had never really vanished from the vicinity. It had not been in the town itself, but in the surrounding district of north-east Derbyshire, but vaccination was less prevalent there now than at the beginning. People had come to discover that an attack of this disease, on the whole, was better than submission to vaccination. It involved quite a pleasant three weeks in hospital, and they received their insurance money. He did not think the disease was worth preventing, at all events if it meant detriment to the true cause of vaccination by describing the disease as loathsome and fatal when it was neither. He had seen 2,000 cases, and had never witnessed anything suggestive of haemorrhagic or toxic phenomena. It had been repeatedly said that the disease was increasing in virulence; he had visited parts of the country from which these statements emanated, and had found no evidence in support of any change whatever in the character of this disease. What Dr. Millard had really meant was that vaccination did not protect the community because the community did not avail itself of the protection. There were communities completely protected because completely vaccinated. He asked Dr. Millard to reconsider his position. If he admitted, as he appeared willing to do, that a community vaccinated and revaccinated 100 per cent. was a community in which he could not conceive a case of small-pox occurring, then he should cease to repeat that vaccination, while protecting the individual, did not protect the community.

Sir WILLIAM HAMER asked the Section seriously to consider whether there was really any evidence that this encephalitis in recently vaccinated children was anything more than a purely fortuitous occurrence.

Dr. R. W. JAMESON said that it was all very well to declare that vaccinia might activate some latent neurotropic virus, but nobody could say that these children who died of post-vaccinal encephalitis would have died had they not been vaccinated. That was the point which would affect the general public. It was asserted that in infant vaccination post-vaccinal encephalitis was not forthcoming, but in children under 1 year old who died the cause of death, which might be put down as marasmus and convulsions, was often not really known. There was no justification for saying that post-vaccinal encephalitis was even uncommon after infant vaccination. The vaccination condition in the case of infants ought to be stated on the death certificate. To talk about vaccination and revaccination in non-epidemic times was just about as practicable as to talk about staying in bed to avoid street accidents. As to propaganda among the general public, vaccinists were not ready to conduct it; they did not know the protective value of vaccination, the duration of the protection, or the infectivity of small-pox. All they knew was that vaccination did confer some temporary immunity, very much more lasting in variola major than in variola minor.

Dr. MAJOR GREENWOOD thought Dr. Garrow illogical in his attack on the logic of Dr. Millard. Much nonsense was talked about vaccination having modified the epidemiological history of small-pox. The fact was that in respect of the whole question of herd immunity as against individual immunity we were as yet only at the very beginning.

Dr. J. A. H. BRINCKER (London County Council) gave a brief account of recent experience amongst London school children. During the last two years this mild small-pox had infected children attending forty-six of the council schools, and in these schools vaccination was performed in so far as the parents consented. Something like 6,000 children had been vaccinated in this way, and until a week or two ago there had been no case of post-vaccinal encephalitis, but during the Christmas holidays one case occurred, with a fatal termination.

Dr. S. P. BEDSON hoped that the possibility of finding a better method of prophylactic vaccination would not remain unexplored. He did not think it possible to popularize the present method because of the fatalities that had occurred, however few in number these might be. Professor ARTHUR ELLIS concurred: he had seen four healthy children who within three weeks were dead of post-vaccinal encephalitis. This very serious condition was recognized by the authorities as far back as 1922, and there had been more deaths from post-vaccinal encephalitis than from small-pox. A more efficient type of vaccination was certainly needed, and a lead had been given by the work on the filter-passing

viruses. Dr. KNOWSLEY SIDLEY asked some questions about the necessity for more than one inoculation, and also as to the origin of the lymph, which last he thought a matter of great importance from the public point of view.

Professor LEDINGHAM, in reply, said that he could not see the logic of Dr. Killick Millard's position, but he was not prepared to discuss the subject; Dr. Garrow had dealt with it effectively. A more safe method of vaccination was, of course, greatly to be desired. These methods of immunization were always somewhat of an experiment, but, happily, human volunteers had never been lacking, and they had rendered fine service. Research on a large scale on post-vaccinal encephalitis had not yet been conducted; it was only of recent years that these serious accidents had occurred. Workers on the subject were in the dark as to why they should have happened, but he could not agree with Sir William Hamer that they were fortuitous.

Reviews.

CHRONIC ARTHRITIS.

IN the preface to his book on *Chronic (Non-tuberculous) Arthritis*[1] Mr. A. G. TIMBRELL FISHER points out the large amount of suffering and disability in this country due to so-called "rheumatic" diseases. The chief medical officer to the Ministry of Health has estimated that this group of diseases is costing the country in sick benefit alone some two million pounds a year, and half of this wastage is due to chronic joint disease. Yet after many years of experience we are not in a position to substantiate any theory of *etiology, pathology, or treatment*; and even diagnosis, as far as classification is concerned, is a subject of dispute. Some forms of the disease have existed since prehistoric times, and for generations they have concerned medical authors and spa physicians, yet therapeutic progress has been small. Mr. Fisher, rightly as we think, would have us go back to Hunterian principles and study with the help of all modern means first the physiology of joints and then the pathology of arthritis, before attempting classification or laying down rules for treatment. He has acted on these principles, and the book before us sets forth clearly the results of his labours.

Beginning with a study of the histology of joint-structures and an experimental investigation of their reaction to injury or toxins, Mr. Fisher goes on to discuss the pathological appearances found in various joints in divers stages of disease. The result of this investigation is the demonstration that, to a very large extent, the changes which occur, *especially in cases of osteo-arthritis*, are of a compensatory or curative nature. Those students of this subject who have been bewildered by the elaborate systems of classification adopted by some writers, notably on the Continent, will be relieved to find that, although he recognizes much variety and many differences between individual cases, Mr. Fisher divides all cases into two broad classes—namely, rheumatoid arthritis and osteo-arthritis. The first type is preponderatingly toxic in its etiology, and likely to be found in those with an hereditary predisposition; the other is caused by trauma and defective nutrition of joint cartilage, *from whatever cause these may arise*. Osteo-arthritis may, however, be secondary to rheumatoid arthritis, the latter acting as a cause of malnutrition, and thus indirectly of a lesion of the joint cartilage and the underlying bone.

As regards treatment, Mr. Fisher lays due stress on the importance of orthopaedic measures in the management of the disease in all its stages. He emphasizes the importance of knowing when and in which cases movement should be encouraged, and in which cases ankylosis in the most favourable position should be aimed at. Operative treatment such as arthroplasty, cheilotomy, and excision receives full consideration. Such subjects as gout and neuropathic joint disease are briefly dealt with, but the author has wisely devoted most of his attention to so-called rheumatic arthritis.

This work represents a most painstaking and illuminating attempt to set the physiology, pathology, and treatment of joints and their disorders on a more sound basis than heretofore. Mr. Timbrell Fisher has established the existence of facts hitherto unknown and has made valuable contributions to our knowledge. His book is to be recommended to everyone who is interested in the study and relief of chronic joint disease. The illustrations are many and excellent.

BEDSIDE DIAGNOSIS.

IN choosing the title *Bedside Diagnosis*[2] for the four handsome volumes which have recently appeared under his editorship, Dr. GEORGE BLUMER's object has been to call attention to the importance of observation by the unaided senses, or at least by the senses aided only by such simple instruments as the clinical thermometer and the stethoscope, and by those examinations which any physician can make without extensive laboratory equipment. In many of the more recent publications, both in this country and in America, there has been a wholesome tendency to stress the importance of purely clinical observation and to combat *the dangerous idea, which threatened to win popularity*, that medical diagnosis was becoming mainly instrumental—an affair of test tubes and x-ray photographs. Dr. Blumer, in his preface, very wisely remarks that new methods of a technical nature are continually appearing, and there is a constant tendency to overrate these in spite of the fact that under the test of wider experience many *of them prove to be of little value*. On the other hand, there will never be a time when the use of the senses will cease to be the most important factor in diagnosis. Thus in the work under review, while all modern laboratory tests are mentioned in their appropriate places, the greatest emphasis is laid upon the methods of complete and thorough physical examination of the patient.

The complete work is a symposium in which sixty-four authors have taken a share, each subject being treated by a specialist recognized as such in his own particular sphere. The art of diagnosis alone is discussed; no attempt has been made to present a complete textbook or to deal with therapeutics. That the subject has been very thoroughly treated is shown by the fact that the articles fill three stout volumes. Volume I is devoted to the infections and intoxications, deficiency diseases, metabolic diseases, developmental diseases, diseases due to physical agencies, such as compressed air, fatigue, heat and cold, and the diseases of *the locomotor and digestive systems. Volume II deals with* the liver and gall-bladder, the pancreas, peritoneum, lungs and bronchi, mediastinum, the circulatory system, the blood, lymphatic system and spleen, and the urinary system. In Volume III are described disturbances of the endocrine system, the nervous system, and vasomotor, trophic, and psychiatric conditions. In each section adequate space is devoted to the discussion of differential diagnosis, and very complete lists of references to original papers are given with each chapter. Each volume is furnished with an index to its contents, while the fourth volume of the series consists of a general index for the whole work—a very useful aid in giving speedy access to any particular point the reader may desire to refer to, and of a size easy to handle.

It would be impossible in a work of this magnitude to review every section in detail; we must be content with noting the general high standard of excellence of the articles; they are uniformly just of the right length for the subjects touched upon, and nothing of real value seems to have been omitted. The subject-matter is presented in a straightforward manner and with very few of those peculiarities of literary style which arouse a feeling of irritation in the English reader. We hesitate to single out any one section for praise, but we may perhaps call particular attention to the chapters dealing with disturbances of the endocrine system. This section is of special interest, and has been handled in a very well balanced manner by the author, Dr. Hans Lisser. The photographic reproductions are very numerous, and have been

[1] *Chronic (Non-tuberculous) Arthritis.* By A. G. Timbrell Fisher, *M.C.* London: H. K. Lewis and Co., Ltd. 1929. (Demy 8vo, pp. xii + 222; 133 figures, contained in 93 plates and the text. 25s. net.)

[2] *Bedside Diagnosis.* Edited by George Blumer, M.D. Philadelphia and London: W. B. Saunders Company. 1928. (Roy. 8vo: Vol. I, pp. xvi + 832, 155 figures; Vol. II, pp. ix + 851, 257 figures; Vol. III, pp. viii + 1053, 388 figures; Index, pp. 143. £5 15s. net the set.)

chosen with a due regard to the points it is wished to illustrate. The x-ray pictures of the sella turcica in abnormal conditions of the pituitary body are really fine, of their kind real works of art.

The four volumes are well printed and bound, and should make a handsome addition to the library shelves of any practitioner, be he general or special.

DENTAL MEDICINE.

MR. F. W. BRODERICK believes he has found the constitutional cause both of dental caries and of pyorrhoea, and under the title *Dental Medicine*[3] elaborates his theories. Briefly, he holds that dental caries is dependent upon a condition of acidosis, and that pyorrhoea is the result of a compensation for an alkalosis. Restating his thesis with regard to dental caries, the author says:

"It amounts to this. That in the compensation of a tendency to an acidaemia there is a drain on the available alkali in the body to neutralize the excess of acid, and that under these circumstances lime salts that are usually provided for such purposes as stabilizing the alkalinity of the saliva, and through this of hypercalcification of the teeth, or of providing the necessary salts for bodily repair and replacement, and all the other purposes for which calcium salts are required to keep the organism in health, are no longer available; that under these circumstances, if local conditions are favourable, a very definite breaking down of the tooth tissue may result, which will terminate in that condition that we designate dental caries."

This, after some two hundred pages of argument, is a rather disappointing presentment of the case. Hypercalcification of the teeth is by no means a proven quantity; and how the very definite breaking down of tooth tissue which will terminate in dental caries is brought about by a saliva of slightly acid *p*H value is not made clear by the author. The determining factor in pyorrhoea is, in his view, an attempt to rectify an alkalosis by the deposition of subgingival tartar from over-alkaline saliva; dirt and infection are not germane to true pyorrhoea, which the author endeavours to show is always associated with a salivary *p*H value of over 7. In considering the application of his theory, Mr. Broderick hopes to produce immunity to dental caries by the avoidance of acidosis, primarily by administration of large doses of sodium bicarbonate, and to pyorrhoea by administration of ammonium chloride, but he warns the reader that the value of the salivary *p*H is dependent on many variable factors. In chapters on civilization as a factor in the problem, and on dental sepsis as a factor in disease, he finds it possible to explain and perhaps rectify a large number of varied disorders by application of his theory—and if he is right dental medicine is indeed a subject worthy of attention.

Our general criticism of a book which will provide much food for thought is that there are too many quotations, and it is difficult to see the wood for the trees.

In common with many others, Mr. F. TALBOT, the author of *Actinotherapy for Dental Diseases*,[4] is seeking a means whereby the constitutional factors of dental disease—caries of the teeth and pyorrhoea—may be utilized as a defensive mechanism, and thinks he has found it in actinotherapy. The general tone of his book is tentative; of local mouth irradiation we read "good results have been reported in the treatment of septic tooth socket and pyorrhoea," and the sum of the argument in favour of skin irradiation in dealing with dental caries and pyorrhoea seems to be "it ought to do good seeing its value in other infective conditions." The clinical evidence which the author offers is not very convincing. The most positive evidence quoted comes from America. Three hundred school children were divided into two groups—control and irradiated. "On reassembling after vacation the latter group showed almost complete arrest of caries, while the former group stood in marked contrast in their progressive caries." The clinical results obtained in pyorrhoea seem to have been less convincing, and the author remarks, "In other cases the disease is so chronic and so dependent upon constitutional conditions that little good can be expected from ultra-violet radiations." But Mr. Talbot has no wish to exaggerate his clinical successes; rather he wants to open out a new field, and his remarks on apparatus and technique, and on the danger signs in the patient, are eminently practical and of themselves make this little book a valuable guide to all who intend practising dental actinotherapy. There is a sympathetic preface written by the late Dr. Robert Knox.

PSYCHOBIOLOGY.

PROFESSOR C. v. MONAKOW and Dr. R. MOURGUE, in their *Introduction Biologique à l'Etude de la Neurologie et de la Psychopathologie*,[5] discuss the problems of neural and of psychic activity and disorder from a purely biological standpoint. They approach their subject along much the same lines as those made familiar to us by the writings of Hughlings Jackson, but in contradistinction to what they term his Spencerian mechanism of outlook they expound a system of dynamic psychobiology. To maintain the same terminology in describing phenomena ranging from the lowliest activities to the highest psychic creations would appear to present insuperable difficulties; indeed, the authors point out the inadequacy of many of our current appellations. Such a term as "vision," for example, is commonly applied, as though with equal appropriateness, to a process in invertebrate animals and in man. Such usage, by ignoring evolutionary history, vitiates clear thinking and leads to the identification of widely different activities. If, as the authors maintain, it is desirable to trace the self-same process throughout its evolutionary levels, and describe it always in the same terms, then clearly our current vocabulary is ill suited to the exposition of biological phenomena. For example, such words as "attraction" and "repulsion," suitable for the description of amoeboid behaviour, do not adequately convey higher activities, such as sympathy and antipathy, of which they are yet the basis. The authors suggest the substitution of the works "klisis" and "ekklisis" to cover the whole range of the activities in question. They use the term "protodiakrisis" to designate what in man we are accustomed to call judgement and discrimination. The term "hormé" they use to apply to the mainspring of instinctive action, the primal urge or "élan vital." Since so-called instincts are modified by experience, they have thought it necessary to differentiate between the primitive forms of instincts, which they term "hormétères," and forms elaborated in the course of development, which they term "noohormétères."

Considerable space is devoted to the discussion of what the authors call "syncidesis" or "conscience biologique," the self-regulative principle of the organism whereby the various instincts are unconsciously valuated. This principle, it is pointed out, may be disturbed by suggestion from without, and the authors discuss in this connexion rationalizations made by the subject of post-hypnotic suggestion, and describe other manifestations of what they term "causalité agglutinée."

The work is in two sections, one dealing with integration of function, the other with its disintegration, the conception of instinct in man forming the central point of their study. The authors define "instinct" in purely objective (indeed, in teleological) terms, which, though probably valuable to the biologist, is of little service to the psychologist, who cannot ignore subjective experience. Freud is criticized for his neglect of morphological considerations, and for his undue attachment to the language of associationist psychology. Kraepelin is criticized on much the same grounds.

We are inclined to feel that the time is not yet ripe for a psycho-physiological correlation to the extent which the authors envisage. Their attempt to establish a uniform

biological conception of both fields of thought is eminently praiseworthy, and although at the outset it may prove somewhat bewildering, there is no doubt that the future will see a great expansion of the territory they have explored.

MILK LEGISLATION.

For some years past Messrs. J. Bibby and Sons, Ltd., Liverpool, the cattle food vendors, have examined samples of their customers' milk in their laboratory, and helped milk producers with their difficulties, legal and otherwise. As a result of the experience so gained, the laboratory manager, Mr. JOHN HANLEY, F.I.C., F.C.S., has, with the aid of other workers on the subject, written Section II of *Bibby's Book on Milk*.[1] The legislation on milk is given fully, together with annotations by accepted authorities and full reports of the most important cases decided. The main theme of the text written by Mr. Hanley is the injustice which he considers has arisen as the result of the Sale of Milk Regulations, 1901, made by the Board of Agriculture. He puts the position very fairly when he says:

"It was, of course, impossible to define minimum chemical limits for the composition of pure milk, but figures were selected distinctly below the average composition of milk, and it was decreed that when milk was found below these figures (3 per cent. fat and 8.5 per cent. for non-fatty solids) a presumption that it was *adulterated or deprived of something arose. This presumption* was really intended to compel the vendor to prove the genuineness of the milk, and is in itself an admission that the analyst cannot tell whether it is genuine or not, but that he suspects it."

He then goes on to assert:

"This presumption and the conceptions underlying it have been so badly misused by some and misunderstood by others that it has become evident that it must be abandoned."

He proposes that—

"The law should be amended so that no seller should be convicted on a charge of selling adulterated milk unless the prosecutor proves that the milk was adulterated and that the seller knew or ought to have known it was adulterated. In cases where the above cannot be proved the whole procedure should be shifted *from the region of criminal law to that of commercial or civil law.* To give effect to this principle there should be an implied contract between milk sellers and local authorities under which the latter could claim a small sum as damages for breach of warranty in any case where milk sold is below a certain standard of quality. . . . The minimum composition stipulated would reasonably coincide with the seasonal variation in milk known to occur in the particular district concerned."

But a large majority of public health workers consider that the present state of the law, as laid down in Hunt *v.* Richardson, is to the prejudice of the public; if the producer can show that the herd concerned gives milk inferior to the standard fixed by the Board of Agriculture he cannot be convicted. The vast bulk of milk produced in this country contains considerably more fat and non-fatty solids than is required by the Regulations, so much so that the advisability of raising the standard rather than the lowering of it might justifiably be considered. It does not seem fair that a producer of so important a foodstuff should be able to place on the market an article which is markedly inferior to that of his competitors and obtain the same price for it. Some large purchasers of milk pay the farmer according to the fat content of the milk: in this book no emphasis is laid on that fact. No one denies that, from time to time, the mixed milk drawn from a herd, and especially the morning milk of a small herd, falls below the standard, but the view generally held is that it then becomes the duty of the milk producer to take such steps as will remove this inferiority. Mr. Hanley points out that any "appeal to the cow" should be made at the next corresponding milking.

NOTES ON BOOKS.

THE third edition of Dr. ELLIOTT P. JOSLIN's book on *The Treatment of Diabetes Mellitus* was reviewed in these columns on February 9th, 1924. At that time insulin therapy was in its infancy, and the author's views on the technique and the indications for its administration would no longer be tenable to-day. The fourth edition,[2] which has been revised, enlarged, and rewritten, brings the account of diabetes therapy up to date. As before, the book opens with a discussion of insulin, but it is a discussion, not of a new agent of unknown potentialities, but of a proved therapeutic technique rapidly approaching stabilization. The author is, however, careful to point out that the treatment of the diabetic has not been simplified by insulin, but has been made more complex. The patient following the course previously in fashion was scarcely affected by small variations in treatment; but the patient taking insulin, to use a metaphor of the author's, is like a rapidly moving machine to which a slight swerve of the wheel will bring disaster. "During the last five years whenever I have read, heard, or seen anything which I felt would be of value in the treatment of my diabetic patients I have recorded it, and later, if on second and third perusal it has seemed worth while, inserted it into this book." This quotation may give some idea of the scope of the book, which deals extensively with the physiology, pathology, diagnosis, and symptomatology of diabetes, the diet of diabetic patients, the surgery of diabetes, and the use of various remedies, such as synthalin, myrtillin, and liver. The chapter on the treatment of diabetes in children is particularly valuable. The great change in the prognosis of diabetes brought about by the introduction of insulin has completely altered the regime of the young diabetic subject; it is now necessary to take long views, to plan a diet and mode of life for many years ahead, in the hope perhaps that, in some cases at any rate, regeneration of the pancreas may occur and the sugar tolerance ultimately become normal.

Professor NELLIS B. FOSTER's book on *The Examination of Patients*,[3] which first came out in 1923, has, after being reprinted three times, been revised, expanded both in matter and by 18 new figures, and slightly increased in price. In this second edition the author has, in response to repeated requests, treated the subject of differential diagnosis in the same concise manner as in his previous description of the methods of examination. The style is attractive, and carries the reader pleasantly along. Thus "Chlorosis has become a rare disease. The substitution of a tennis racquet for a fan has severed kinship between the modern girl and her sister of the eighteenth century novel," and "When there is a suspicion of empyema of the pericardium the question should be decided by puncture. Timidity in tapping the pericardial sac costs many lives." The succinct account of tularaemia bears witness to the revision; on the other hand, in a new footnote on pernicious anaemia, Knud Faber is instanced as prominent among those who consider achylia as the cause of the disease: this is perhaps too definite, for Faber, while admitting that achylia is the most frequent cause, states that it is not the only cause, and insists on a continually recurring intoxication, usually by a protein of intestinal origin, as the essential factor. As a whole the work fully justifies its obvious popularity in America.

With the idea of providing a volume on therapeutics which should be more than a list of suitable drugs, the late Dr. A. MARTINET and Dr. P. DESFOSSES have edited the prescriptions of a general practitioner,[4] using the term "prescriptions" in the widest sense to include everything which the patient must be told. They have the collaboration of thirty authorities, who contribute in all 250 examples. Each of these, under the name of some disease, deals first with the regime as a whole which the patient must adopt, with details as to diet and physiotherapeutic measures. Then follow drugs set out in prescription form, and in certain examples local and systemic treatment are dealt with separately. Indications for special forms of treatment, such as at a spa, follow in some instances. The whole work is well planned, and the introductory example of a general scheme for ordering treatment gives a very clear summary of what a practitioner ought to do.

We have perused *Muter's Short Manual of Analytical Chemistry*[5] and observe that it deals with an extensive field of chemistry within the limits of a comparatively small space. This would appear to be the cause of its chief defect, for while it treats of subjects too numerous for the beginner to deal with, the treatment is not sufficiently precise for the more advanced student. It appears to be intended mainly for students of pharmacy. We think that, useful as the book may be in leading the student to make experiments, he would be well advised not to regard it as the only book he will need, but should rather use with it another work as companion for the sake of obtaining a second view of the chemical facts from another aspect.

A STUDY OF THE MENINGOCOCCUS.

IN a monograph[1] just published Mr. E. G. D. MURRAY of the Department of Pathology, University of Cambridge, gives the results of a close, sustained, and critical scrutiny of the general biology of the meningococcus and of its reactions to its environment. Investigations of the meningococcus conducted during the war generally had a strictly utilitarian purpose; inquiries centred round the problems of the meningococcus as an infective organism, the genesis of the outbreaks of cerebro-spinal fever, and the specific treatment and control of the disease. The detailed bacteriology of the meningococcus and the tolerance and antagonism it meets in the animals it infects; the methods of altering its virulence in artificial media; its cultural requirements; the properties of its endotoxin—these more academic problems, necessarily studied only incidentally in the period 1915–18, have been investigated since the close of the war by Mr. Murray, working under the auspices of the Medical Research Council. A great part of his monograph is occupied with a detailed account of the distribution, morphology, and physiology of the meningococcus, the latter being concerned with its reproduction, cultural characters, and conditions, its fermentation reactions, and its synergic and antagonistic relations with other bacteria. It is interesting to note that the meningococcus seems to be very intolerant of association with other bacteria, both *in vitro* and *in vivo*, a synergic reaction invariably favouring the other organism, and antagonism always being against the meningococcus.

Action of Antiseptics.

Interest in the feeble though varied resistance offered by the meningococcus to antiseptics has been stimulated by the desire to disinfect the nasopharynx of carriers. Weichselbaum has stated that 1 in 22,500 formaldehyde rapidly destroys the meningococcus, and that 1 in 800 phenol hinders its growth. Dopter showed that while a wide range of antiseptics, including mercuric chloride, creosote, lysol, menthol, and formalin, rapidly kills suspensions of meningococcus cultures, others—for example, hydrogen peroxide and wintergreen—are without even inhibitory effect on growth; the most powerful effect he found was produced by eucalyptus. Gordon and his colleagues, in the course of experiments on the disinfecting power of an atmosphere heavily charged with chloramine-T, found that they were able to obtain striking effects both in freeing heavily infected carriers and in reducing the carrier rate in depots where it was high. This method, though producing only a limited fall in the carrier rate, and indeed leaving a considerable residue of carriers after the sprayings have stopped, may have value in keeping down the carrier rate when it is not possible to avoid overcrowding a susceptible population beyond the limit of safety.

Virulence.

The definition of virulence as "the capacity of the bacterium to live and multiply in the living tissues of the host" assumes a potentiality in the bacterium independent of any contributory action on the part of the host. It involves the further assumption that to combat virulence the host must acquire new-formed defence mechanisms; and to explain the varying incidence of the disease a hypothetical "susceptibility" in which individual subjects differ among themselves has to be invoked as well. Such assumptions, in Mr. Murray's view, merely serve to confuse the issue. The defensive forces of the host are primary and secondary. Of the first kind are the adaptations of its physiological processes designed to deal with physical and chemical accidents, and to eliminate unwanted metabolites; other primary agencies are the processes of repair, of excretion, and selection; secondary forces comprise the immunity responses. The defences of the bacterium against the attack of the host involve resistance to phagocytes, rapidity of multiplication, the formation of toxins, and interference with the circulation of the blood and lymph. Failure of the immunity responses of the host may be due to damage to specialized cells by a high concentration of the bacterial forces. In Mr. Murray's view virulence is the resultant of the opposed systems of forces exerted physiologically by both the parasite and its host in the efforts of each to maintain its life and health. Such a definition, besides absorbing the observed facts, has the further merit of delimiting two main lines of investigation—namely, the measurement of the "resultant force" (virulence) and its direction, and the analysis of the contributing "forces" of both parasite and host. Virulence is measured by determining the minimal lethal dose of the living culture by a stated route in a given variety of animal. For the meningococcus it is suggested that the most satisfactory test is the determination of the least amount of viable young culture which, injected intraperitoneally in a single dose, will cause the death of 20 grams of mouse within forty-eight hours.

Determination of Minimal Lethal Dose.

In determining the minimal lethal dose it is necessary to take into account the extent to which the bacterium causes natural disease in the available experimental animal, and the nature, degree, and rapidity of alteration that may occur in the bacterial culture under the conditions imposed by growth on artificial media. Thus in working with the meningococcus the most useful animal is the mouse, in which death takes place within forty hours in response to a dose large enough to be measured with sufficient accuracy. Allowance must be made for attenuation by subculture, and the rapid variability of the fatal dose, by virtue of which animals may resist as much as ten times the mass of cocci which on a previous occasion was lethal. By controlling a variety of conditions—for example, the viability, the purity of culture, the constitution of the media, the phase of growth, and the age and subculture—Mr. Murray has found it possible to establish a minimal lethal dose for the meningococcus which ranges between 8 milligrams and 0.5 miligram for 20 grams of mouse.

Alteration of Virulence by Animal Passage.

In attempting to raise the virulence of the meningococcus by intraperitoneal passage Mr. Murray found great difficulty in recovering the organism from the peritoneal exudate of mice which had succumbed to a large dose of a culture of low virulence. Resort to cultures of higher virulence did not remove this difficulty; nor was it affected by using alternating cultivation and passage, or direct transference from mouse to mouse. Almost invariably, however, Mr. Murray found large numbers of meningococci together with masses of phagocytes in the tightly rolled up omentum of the experimental animal. When a mouse dies as the result of multiple intraperitoneal minimal lethal doses of a moderately virulent strain, very large numbers of healthy-looking meningococci, of which comparatively few are intracellular, are found in the peritoneal exudate. Their presence depends on the animal having received an overwhelming dose, the number of cocci decreasing noticeably as the dose is diminished. The influence of increased doses is to augment the number of cocci, mostly extracellular, in the peritoneal exudate, though the above-mentioned relation to mass of dose can still be made out. The numerical and qualitative relation of phagocytes to cocci has an important bearing on the type of infection. When the total mass of cocci is small the cells for the most part stain normally; when large, only few healthy cells are to be seen. The phagocytosis is shown to depend on the ingestion of cocci, interference with leucocytes which prevents their active participation in the combat not only, resulting in the presence of more free cocci but in less damage to the cells. When mice recover the majority of cocci are intracellular, the presence of free cocci and the degree of cellular damage again depending on the mass of the dose.

Evidently, then, the leucocytes play an important part in combating the infection, and it should be possible to raise the virulence of the meningococcus by intraperitoneal passage. Mr. Murray frequently observed, however, that the virulence of a strain recovered from animals would on one occasion be raised and on another lowered, and that there was great variation in the number of viable

[1] Medical Research Council. Special Report Series, No. 129. Price 1s. 6d. net.

organisms discoverable in animals even when the strain which killed them was highly virulent. He assumed, as a working hypothesis, variation among individual cocci whereby some might be more likely to reproduce robust offspring than others, and that the phagocytes and leukines might exercise a selective action. If only the cocci of considerable parasitic capacity survived, the maximum virulence of a strain could be obtained in a single passage; should, however, the resistance of the host be low it would be possible for cocci of mean virulence to grow and even to gain the majority, and so the virulence of the recovered strain would be unchanged or even lowered. Thus the relation between virulence and animal passage is essentially a matter of chance, and it appears impossible to reproduce at will exactly the conditions required.

Interference with the Defence Mechanism.

Mr. Murray found that a dose of meningococcus which failed to kill the standard mouse, and which on microscopical examination proved to be almost completely phagocyted, invariably proved fatal to mice which had received 5 mg. of carmine, preferred by the leucocytes to meningococci, and that the vast majority of cocci were then extracellular. It is thus possible to make a culture appear more or less virulent by active interference with the defence mechanism of animals of average resistance. There is further some converse evidence that the apparent virulence may be decreased by augmenting the defences of the host, thus leading to the conclusion that virulence is not a property of the parasite alone, but the resultant of the physiological forces exhibited by both parasite and host.

Toxin.

Probably in those animals which die as the result of the injection of meningococci, but in which meningococci cannot be demonstrated, the cause of death is the massive liberation of endotoxin by the rapid lysis of the cocci. The presence of endotoxin is demonstrated by the fact that a specially prepared culture free of viable cocci, injected into the animals, proves fatal in a dose which varies from one preparation to another. The amount constituting a lethal dose of intact killed cocci is invariably larger than that of living virulent cocci, a disparity which is more accentuated the more virulent the strain. Further, the lethal dose of intact killed cocci is much larger than that of lysed killed cocci. In the quantitative studies of meningococcus endotoxin it is important to ensure the breaking up of all the cocci present and the liberation of free unaltered contents. Though these conditions have not yet been realized, Mr. Murray demonstrates the possibility of improving certain known methods with ultimate hope of success.

Relation of Endotoxin to Virulence.

Though endotoxin production varies considerably in different strains, any given one will produce endotoxin of as high a value at the end of years of subculture as it did at the beginning. On the other hand, Mr. Murray suggests that it is impossible to persuade a poor producer of endotoxin to improve its product. The production of endotoxin is apparently independent of the loss of virulence by the strain in culture, and is not increased by greatly increasing the virulence of the strain.

Immunity Reactions.

Bacteriologically, anyone harbouring the meningococcus is infected, and the development of the disease to the point at which the reaction of the host appears as signs and symptoms is merely a matter of degree. From this point of view very few people are immune, and from the high carrier rate discoverable under favourable conditions it is evident that their chances of infection depend on the intensity of their exposure. Probably the main natural defence is phagocytosis, the meningococcus being extraordinarily susceptible to lysis within the phagocyte. If there is sufficient inflammatory exudation probably bacteriolysis by alexine comes into play; since the meningococcus exhibits a low order of virulence these natural defences are usually effective.

Acquired Immunity.

Although immune bodies have been demonstrated in the blood of cases of meningitis by a number of workers, the outstanding feature of their investigations is the irregularity of the results. The development of agglutinating power of the patient's serum may fail altogether, and its presence or absence bears no relation to the prognosis. There seems evidence to show that with the serum of cerebro-spinal fever cases phagocytosis is more marked than with normal serum, but the findings of the opsonic test are unreliable because of the many pitfalls in technique. Various workers have demonstrated a complement fixation reaction, but generally without any indication of the agglutinating type of coccus concerned. It has further been shown that the serum of cerebro-spinal fever patients is more definitely bactericidal than normal human serum. Mr. Murray discusses in detail the identification of the meningococcus by its agglutination reaction and the classification of the various strains into distinct bacterial types.

The Production of Antiserums.

In a review of the methods used for estimating the potency of antimeningococcus serum Mr. Murray concludes that the reactions of greatest importance are: (1) the capacity of the serum to neutralize endotoxin; (2) its ability to promote phagocytosis of virulent cocci in the presence of alexine; and (3) its bacteriolytic power. At present, he says, there appears to be very little attempt to standardize antimeningococcus serum, a neglect which is reflected in the therapeutic inefficiency of many of the serums used.

Infection.

In 95 per cent. of all cases of cerebro-spinal fever infection results from contact with the so-called "healthy" carrier. Overcrowding in sleeping quarters offers the greatest danger by shortening the distance between man and man, thus tending to produce a higher carrier rate in a community and facilitating the transmission of infections of the upper respiratory passages. Mr. Murray classifies carriers as primary and secondary, the former being persons with infection of the nasopharynx, but who have not developed meningitis, the latter those who have recovered from meningitis but still retain a nasopharyngeal infection. Primary carriers are further classified as "contact carriers" and "non-contact carriers," the former denoting persons associated with a case, the latter those found in the general population. The contact carrier rate is usually higher than the non-contact carrier rate, but under conditions favouring epidemics these two rates may approach one another very closely. A rise of the non-contact carrier rate to the order of 20 per cent. is a sure "storm signal" of imminent trouble. Primary carriers are, for the most part, infected only temporarily; within six weeks 90 per cent. are free from infection, the remaining 10 per cent. showing varying degrees of obstinacy, though only about 2 per cent. continue to carry over six months or longer.

ROYAL MEDICAL BENEVOLENT FUND.

As grants are made from the income received from subscriptions and donations, subscribers are asked to forward their contributions during the first quarter of the year rather than later, in order that the amount available for distribution may be known and a possible overdraft at the bank avoided. Subscriptions and donations should be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

At the last meeting of the Case Committee thirty-five applications were considered, and thirty-two grants were voted, amounting to £951. The following short summary gives three typical cases.

Widow of M.R.C.S. who died in 1925, leaving her with two children—a girl, aged 16, and a boy, aged 13. The widow is now supporting herself in domestic service. The Fund was asked to assist in the education of the two children, £5 being required for the boy and £36 for the girl for her last two terms. Voted £20 to each child; the Fund is arranging with other societies to contribute the balance.

Wife, aged 38, of L.M.S.S.A. who has had a complete mental breakdown and is subject to dementia paralytica. The wife has no private means and has a girl of 7 to educate. Her father-in-law is making an allowance of £39 a year, the Freemasons £25, and other charities £15, making a total of £79. Fund voted £26, and has referred the case to the Guild to arrange for the education of the child.

Daughter, aged 65, of M.R.C.S. Since her father died the applicant has lived on £53 a year, bad eyesight and deafness having prevented her from working. In consequence of her privations her general health has suffered, and owing to her increasing infirmities she will soon require someone to attend to her wants. Her income has recently been increased to £75 a year. Fund voted £26.

SATURDAY, FEBRUARY 2ND, 1929.

NEUROSIS AND ACIDOSIS.

THE "nervous child" seems to be attracting to itself almost as much attention from paediatricians as it demands in the domestic circle; nor is this to be wondered at, for the vagaries of nervous children are such that the medical attendant is in danger of losing credit at least as much as the harassed parents themselves. We may piously hope that these patients will fare better in an atmosphere of scientific investigation than they do in the limelight of parental solicitude, yet it is painfully evident that the medical aspects of the problem of neuropathic children are interpreted very variously to-day by different authorities.

Dr. H. C. Cameron, who has written so illuminatingly on the problem of the nervous child, now presents, in the lecture published this week at page 185, a study of the metabolic instability to which he thinks these patients are peculiarly prone, and on which he lays great stress from the point of view of the prevention and treatment of many of their troubles. His thesis is that nervous children, because they are nervous, are particularly liable to acidosis, and that this acidosis in its turn exaggerates and precipitates the nervous symptoms and attacks. He regards the nervous child as living upon the verge of acidosis, in a condition, as he calls it, of "smouldering acidosis," which the accidents of its ordinary existence may render a positive factor in the production of active symptoms. With this twofold association of neurosis with acidosis, and of acidosis with neurosis, the vicious circle is complete. Particularly interesting is Dr. Cameron's suggested explanation of why the nervous child is so subject to acidosis. He thinks—though he admits that it is no more than speculation—that the association is attributable to adrenal exhaustion. He surmises that the restless, overactive, overemotional state of the nervous child is responsible for the tendency towards adrenal exhaustion, and that this leads to defective carbohydrate storage and thus to imperfect fat metabolism and acidosis. So close does he regard the etiological association between the nervous diathesis and acidosis that he does not hesitate to speak of "the child with an inborn tendency to acidosis." On the other hand, Dr. Cameron regards the acidosis as producing and exaggerating the nervous symptoms, and the list of troubles which, in his opinion, owe their development or appearance to latent or declared acidosis is indeed a long one. Bouts of vomiting, attacks of mucous diarrhoea, exacerbations of nervous habits, periods of languor and exhaustion, are, perhaps, easily attributable to acidosis, but Dr. Cameron would go further. He suggests that asthma may be closely connected with acidosis, and that the time of its occurrence corresponds with a positive wave of that condition. He is inclined also to attribute to latent acidosis the muscular atony of some nervous children, and thus to include such complaints as flat-foot and greenstick fractures within the syndrome of symptoms. The treatment to be based on this theory of latent acidosis consists in the administration of carbohydrate, most advantageously given in the form of glucose, the regular use of alkaline drinks, and the limitation of the intake of fat. For this line of treatment Dr. Cameron claims considerable success, both in the prevention and the relief of nervous symptoms in children.

Such, then, is Dr. Cameron's conception of the problem of the nervous child. Reduced to its lowest terms it consists of three parts. First, there is presupposed a nervous diathesis; secondly, this induces a latent or positive toxaemia, if this word be used in a sense sufficiently broad to include the set condition of acidosis; thirdly, this in its turn produces further nervous disturbances. Expressed in such terms it must be admitted that Dr. Cameron's theory has the advantage of simplicity. But experience prompts us to wonder whether any simplification, however attractive, will loosen all the knots in the tangle.

Others have written on the question of the nervous child, and for the most part, like Dr. Cameron himself, they have been conscious of two etiological factors—one psychological and the other toxic. In a memorable lecture on the problem of the "solitary child" Dr. Robert Hutchison sketched the psychological effects upon these children of their isolation and the overbearing anxiety of their parents. He was dealing with selected children, but, as we understand his view, he held that the psychological atmosphere of the "solitary child's" home life was too unhealthy for its nervous system, and so originated nervous symptoms. Here the psychological factor is all-important, the diathesis of secondary importance, and the toxic factor absent or at least non-essential. Then at the Bath Conference on Rheumatic Disorders last May Professor C. Vining spoke of the "pre-rheumatic" child, describing once more the type of patient whom Dr. Cameron speaks of as the "nervous child." Here were emphasized the nervous diathesis and rheumatic toxaemia as the two factors at work. Not long ago in our columns Dr. Reginald Miller[1] brought forward what he called the "intestinal child," the child rendered ill by alimentary toxaemia. He, too, wrote of the nervous child, and, indeed, definitely claimed many of the so-called "nervous" children as belonging to this group. Here the toxaemic element is stressed as all-important, the nervous diathesis being a factor, though not an essential factor, in the production of nervous symptoms. Quite recently we published a paper by Dr. A. A. Osman,[2] who takes very much the same line as Dr. Cameron in attributing the symptoms to acidosis, but says that as many as 30 per cent. of hospital children over the age of 2 years suffer from acidosis and cyclical vomiting. Lastly, there are the claims of psycho-analysis to provide an explanation in terms of repression and the "dynamic unconscious."

We see, therefore, that there is considerable disagreement as to whether underlying the nervous instability of children the essential factors are physical or mental. Furthermore, even among those who agree about the etiological significance of toxaemic states there is great diversity of opinion as soon as the actual nature of the toxaemia comes under discussion. It is from considerations such as these that we are constrained to wonder whether Dr. Cameron's simple explanation, with its exclusive reliance on acidosis as the main underlying factor, will be found to cover all the aspects of this complicated problem.

PLAGUE AS AN INTERNATIONAL PROBLEM.

THE International Health Office (Paris) regards the international control of plague as one of its main functions. To keep abreast of modern knowledge of the numerous rodents and fleas which play a part in spreading this disease among men and animals it has arranged for the compilation of a series of reports, and has published these in book form.[1] The matter no longer relates only to the rat and its particular flea, *Xenopsylla cheopis*, and this inquiry has enabled the International Committee to prepare a useful directory of the rodents and fleas incriminated in various parts of the world. In the first paper Professor Ricardo Jorge of Portugal sums up the available information. There is an initial difficulty in the nomenclature of the subject, for the term "rodent" is in common use for all the animals which form a reservoir of plague; many species included in the natural order of that name play no part in the dissemination of the disease, and not a few outside it are as culpable as the rat. There is, moreover, little unanimity in the application of generic and specific names to those animals known to suffer plague epizootics and those fleas agreed to be transmitters.

The rodents of importance internationally are *Rattus rattus*, the black rat, and *Rattus norvegicus*, commonly called the brown rat. Jorge uses the generic name *Epimys*, which is unfamiliar in Britain, and he comments on the confusion which arises from the use of the adjectives of colour to indicate species. Sometimes the black and brown rats are called brown and grey respectively, and there are, in fact, "black" rats which are brown, "brown" ones which are black, and grey rats of both species. An interesting note on the history of the replacement in Europe of *rattus* by *norvegicus* disposes of the idea originally held that it was this change which determined the disappearance of devastating plague epidemics in that continent and in England. Plague had ceased to be a public scourge in these places long before the native rat had been driven out by the invading brown rat. Jorge attributes the change in plague prevalence to the natural variations in incidence exhibited by many diseases, and to the general hygienic improvements which have accompanied civilization, but he draws attention to the theory of Hirst (Ceylon) that the altered distribution of plague outbreaks is correlated with a changed geographical distribution of the flea *Xenopsylla cheopis*. Nowadays *norvegicus* predominates in Europe, but *rattus* is numerically superior in Africa and Asia, forming 98 per cent. of the rat population of India. In Egypt *alexandrinus* (a subspecies of *rattus*) occurs with the brown rat, which, by taking advantage of shipping, has made its way up the Nile. Palestine has the black rat, except in the ports, but the brown has achieved supremacy in Algeria, Tunisia, Mauritius, Iraq, and the Straits Settlements, and is in the ascendant at Bombay, Hong-Kong, Japan, and Dakar, while the black is in excess in Ceylon. In Australia *rattus* exceeds *norvegicus* by 40 to 1. There are signs that the black rat is again increasing in some of the areas of Europe where formerly it prevailed.

Spermophiles (small marmots, many species of the genus *Citellus*) form the animal host in the steppes of south-east Russia, and Jorge comments on the curious fact that in this area mice, though abundant, do not act as plague carriers. In southern Russia, however, both field and house mice form the chief source of human plague, though nowhere else have house mice been convicted of playing such a part. Three papers from Russia,[2] published since the report under review, suggest that perhaps some of the conditions described there as plague in man and in animals may have been tularaemia. It has never seemed likely that tularaemia was limited to North America; its occurrence in Japan seems to have been confirmed, and the Russians now describe certain plague-like conditions which may, indeed, be tularaemia. The water-rat, *Arvicola amphibius*, is particularly concerned. South Africa has special problems of its own, with a large number of wild animals naturally infected, among them the gerbille, from which infection is acquired by the multimammate mouse (*Mus coucha*), which in turn, in its visits to human habitations, passes the disease to man. In Manchuria and much of north-eastern Asia the fur-bearing marmot is the animal which keeps plague always alive, while ground squirrels have been shown to suffer from chronic plague in North America.

The reports collected here leave little doubt that chief importance as a transmitting agent has been rightly attached to the rat-flea *Xenopsylla cheopis*, but the vexed question of the part played by *X. astia* still remains unsettled. Hirst's work in Ceylon would seem to acquit *astia* of serious harm, but Graham and Mital, reporting here from India, give data which are difficult to reconcile with innocence of that flea. The report from the United States of America describes the calculation of an index of epidemicity. Some reserve is expressed regarding the reliance which can properly be placed on such numerical representations of the probable behaviour of a disease, but if such indices are to have any importance at all they must be founded on better and more numerous data than some flea-occurrence figures which were recently thought worthy of publication in the official U.S.A. *Public Health Reports*.

Colonel Forster contributes a paper on the forecasting of plague epidemics in India, in which plague occurrence and mortality are studied in relation to weather conditions. Such attempts at prophecy have lately been much in vogue in India, and it is perhaps legitimate to invite publication of these forecasts so that the value of the work may be put to the test. The reports submitted by the countries where plague is still a menace are very full for the most part, and represent a valuable addition to the literature of the subject. Roubaud contributes a chapter giving a systematic description of the main types of fleas of rodents, and the book ends with a useful alphabetical list of the animals—true rodents and others—which are known to be reservoirs of plague virus.

THE TRAFFIC IN DANGEROUS DRUGS.

EVER since the International Opium Convention of 1912 was signed at The Hague attention has been called in these columns to the enormous excess of production of drugs of addiction, such as opium, morphine and its derivatives, and cocaine, over any conceivable medical requirements. The effect of this surplusage in providing for illicit traffic, at huge profits, and the prostitution of these drugs to vicious and criminal purposes, has been reiterated. We welcomed the cessation of the export of Indian opium to China, and questioned the consistency of continuing the

preparation and export of prepared opium (for smoking) to the Far East by the Government of India. We accepted the Dangerous Drugs Acts of 1920 to 1923 as carrying out for this country the legislation implied by the terms of The Hague Opium Convention, and have urged that similar legislation should be introduced and made operative by all other signatory powers. We have suggested that some practicable measures should be devised for controlling *at the source* the production and manufacture of these dangerous drugs, as well as for the control and supervision of traffic therein, whether national or international. We have noted with regret that in China, at a time when opium production for a period appeared to be coming to an end, the outbreak of civil war in that vast territory should have been accompanied by a great recrudescence of the cultivation of the poppy. We have also from time to time called attention to the way in which China has been literally drenched with morphine and cocaine exported from European countries. Singularly complete exemplification and justification of the foregoing contentions have been furnished by the latest disclosures of the Opium Advisory Committee of the League of Nations. It appears that the Dutch Government has unearthed a factory in Holland which imported huge quantities of morphine, heroin, and cocaine from Switzerland, and purveyed them, chiefly through Viennese agents, to the Far East, the bulk being consigned to China. The amounts of the drugs handled by the Dutch firm—now happily suppressed—were stated to be 35,600 ounces of morphine, 113,000 ounces of heroin, and 3,250 ounces of cocaine. Mr. Sato, the Japanese delegate, shrewdly remarked that "it was impossible to deny the justice of the Chinese demand that the flood of morphine and heroin into China should be considered at the same time as the flood of opium out of that country." It is difficult to understand how this huge illicit traffic got through the meshes of the import and export certificate scheme devised by the Opium Advisory Committee. The new permanent Central Control Board, which has at length been set up under the Geneva Convention of 1925, will have its work cut out for it. In view of these new disclosures it is perhaps to be regretted that, as stated by the president of the conference which gave birth to that Convention, "the American principle for a limitation of production to medical and scientific purposes has not been included as a contractual obligation."

GLANDERS AND MELIOIDOSIS.

ALTHOUGH for some years glanders has been absent from this country, and is everywhere receding before the advance of civilization, it is still of sufficient importance in medicine to have formed the subject of a joint discussion between the Tropical and Comparative Medicine Sections of the Royal Society of Medicine on January 23rd. Until recently, of course, the disease was no uncommon one in Britain: less than twenty years ago there were about 1,800 equine cases in London each year, and about four human deaths in the country generally. Its eradication has been due mainly to the intelligent use of mallein, one of the few really reliable diagnostic agents in the service of man. This disappearance of the disease in temperate climates has rendered its bacteriological study more difficult, and modern workers find that there are many deficiencies in our knowledge of glanders and kindred diseases. *Bacillus malleï* is not now regarded as a single well-defined type, but as a member of a group of organisms, some of which, notably *B. whitmori*, the cause of melioidosis, have been differentiated on various grounds from the type. The distribution of the various serological races has still to be worked out, however. True glanders, due to *B. malleï*, is essentially an equine disease; cattle, pigs, rats, and mice appear to be naturally immune. Closely related to glanders, and apparently limited to Burma, the Malay States, Ceylon, and Indo-China, is a peculiar condition called by its discoverers, Drs. Stanton and Fletcher, melioidosis. This is primarily a disease of rodents, and it is always fatal to guinea-pigs, rats, and mice, as well as to carnivores. The horse and the pig, on the other hand, are very resistant, and only suffer from localized infections at the site of inoculation. Small ruminants and monkeys are susceptible, as also are human beings. In man, as Dr. Fletcher explained at the meeting, the result is generally fatal. He estimates that about two hundred human cases occur annually in the Malay States, but these are often wrongly diagnosed owing to the bewildering variety of symptoms produced—it has been mistaken for malaria, cholera, acute mania, plague, enteric, dysentery, tuberculosis, bronchitis, and pneumonia, among other conditions. The essential lesion, as in glanders, is a minute characteristic nodule which may caseate (in the lungs) or suppurate (in the liver). The organism, closely related to *B. malleï*, may be distinguished from it by being actively motile in young cultures, by its profuse growth on ordinary media, and by its characteristic growth on glycerin agar. The other diseases of the horse which clinically may resemble glanders—such as epizootic lymphangitis, ulcerative cellulitis, strangles, and so on—are of little importance to the clinician, and with the exception of the first-named are not transmissible to man. All can be easily distinguished from true glanders by means of mallein. This agent, prepared from the bacillus in a manner analogous to tuberculin, is, rightly used, considered to be 100 per cent. effective, and its continued use by veterinary surgeons will maintain our freedom from one of the most painful and fatal diseases which can affect man. Few human patients recover from it, and fewer still are in a position to describe it accurately, as did Professor Gaiger at the joint meeting mentioned. He contracted the disease in India many years ago, and it was only after eighty-two operations, during one of which an arm was amputated, that he completely recovered. Since then, however, attempts have been made to find a curative serum—vaccines are obviously useless in an acute generalized condition such as this—and recently one such has been prepared in Canada by injecting horses with mallein. It has been used on a few human cases with good results. Fortunately glanders is now very uncommon, and the use of this remedy is seldom required; but a similar serum prepared from *B. whitmori* would not be without interest in the treatment of the relatively much more common melioidosis in the Middle East.

TREATMENT OF RINGWORM OF THE SCALP BY THALLIUM.

THE remarkable property possessed by thallium, even when employed in quite moderate doses, of causing total though temporary alopecia, has long been known, and has proved an insuperable objection to the use of that metal in medicine, notwithstanding its value in the treatment of certain gastric conditions and in controlling the night sweats of phthisis. But Sabouraud, apparently at about the beginning of the century, although he did not publish the results of his tentative efforts until 1910, recognized that through this very property thallium might prove to be effective in the treatment of ringworm of the scalp. By means of thallium he actually cured several cases, but was deterred from its further use by the serious toxic phenomena which occasionally supervened. Subsequently, as we all know, he developed the *x*-ray treatment of ringworm with such success that thallium once more fell into obscurity. Dr. J. G. Urueña,[1] while admitting Sabouraud's priority, claims for Mexico the distinction of being the first nation to *systematize* the use of thallium for the

[1] *Le Traitement des Teignes par l'Acetate de Thallium.* By Dr. J. G. Urueña. 1928. Masson, Paris.

treatment of ringworm of the scalp. In 1918, owing to the shortage of *x*-ray tubes caused by the war, the Mexican authorities, harassed by the prevalence of ringworm and favus among their population, were compelled to seek some other method of treatment, and fell back on thallium acetate, and it appears that Professor R. E. Cicero, then in medical charge of a ringworm school, was the first to employ it as a routine method of treating both ringworm and favus. His preliminary results were communicated to the Academy of Medicine of Mexico on March 5th, 1918. At first he employed a dose of 5 mg. per kilo of body weight; this, however, was found to be too small to obtain a satisfactory epilation with certainty, and subsequently the dose was increased to 8 mg. per kilo, an amount which was found to give good results without risk of serious toxic complications. Since then this method of treating ringworm has been in constant use in Mexico, and has also been introduced into Europe with success. British dermatologists, however, do not seem to think so highly of it as some of their American and Continental colleagues. Perhaps the explanation lies in the fact that, as Dr. Urueña himself states, thallium is not so successful in cases of microsporon ringworm—by far the commonest type in this country—as it is in the various sorts of large-spored ringworm which form the majority of cases elsewhere. In this country, we think, the principal field for the employment of thallium is in children too young to be submitted to *x* rays. In older children there is a greater likelihood of serious toxic effects; in fact, there is a maximal dose for any patient, however heavy, of 0.3 gram of thallium acetate, which is almost invariably sufficient to produce a satisfactory defluvium of the head but not of the body.

THE CAMPAIGN AGAINST RHEUMATISM.

THE January number of *The Cripple*, which has recently appeared, is the second issue to be made since this periodical adopted both a new name and a new editorial policy. An account of these developments and of the main features of this change was given in the *British Medical Journal* of November 10th, 1928 (p. 859), and we commented on the practical advantages which the broader basis and wider outlook would secure. The current issue of *The Cripple* marks another forward step in this respect. Mr. R. H. P. Orde, director of the Central Bureau of Hospital Information, contributes a lucid and stimulating article on the development of the campaign against rheumatism and the part played in it by the British Red Cross Society. He traces the growth of this campaign since the Ministry of Health, in 1922, undertook the investigation of the incidence of rheumatic diseases; this revealed the magnitude of the question for the first time, and led to the successful appeal by the Red Cross Society for £40,000 for the establishment of a central clinic for physical treatment in London; the clinic will, it is expected, be opened in the middle of the current year. This is admittedly only one stage in the campaign, and attention is now being paid to future developments. Mr. Orde remarks that a central clinic cannot work in isolation, but must be associated with numerous other organizations for treatment and research. Moreover, central clinics cannot be multiplied indefinitely; their high cost alone makes this impossible. It is suggested, however, that in many cases one or two visits to a central clinic may be sufficient to ascertain the nature of the complaint and to indicate the necessary treatment; in some instances this may be available only at the central clinic, but in others—possibly a considerable proportion of the whole—effective therapeutic procedures may be made available at smaller clinics, of which already there are sufficient to demonstrate their value. Some are orthopaedic clinics associated with definite orthopaedic schemes, and others are Red Cross clinics undertaking a certain amount of orthopaedic work and treating other conditions largely of a rheumatic character. There are in the London area to-day four clinics of this latter type. Mr. Orde describes the methods of work and constitution of such units, and, in conclusion, outlines his conception of the form which the campaign against rheumatism should take. He proposes that it should be based upon central clinics, which should be situated where advantage may be taken of existing treatment facilities, in association, for example, with spas, voluntary hospitals, or municipal establishments. Where facilities do not exist, and there is a real need, the establishment of *ad hoc* clinics should be the task of the Red Cross Society. Associated with the central clinics there should be auxiliary clinics, developed from existing institutions where possible, or formed for the purpose, carrying out the simpler forms of treatment. Each Red Cross area might constitute an independent unit, thus permitting elasticity in organization, but Mr. Orde thinks that the formation of a central fund to supplement local efforts would be desirable at the beginning. It is thought that such a scheme offers a practicable method of providing for the treatment of rheumatism within the limits of the voluntary system; its efficacy can be determined finally, of course, only by the test of experience. Within the organization proposed it would certainly be possible to utilize the existing machinery to the best advantage. As in so many other similar problems, the main difficulties likely to be met are in connexion with finance; one of these arises from the fact that in many of the areas where the need is greatest industrial depression has made the raising of funds for voluntary effort least easy. Probably in such cases special contributions from the national fund proposed by Mr. Orde would be available. His scheme is certainly worthy of careful consideration. The remainder of the matter in *The Cripple* maintains the high standard of the previous number. Dr. P. C. Varrier-Jones continues his articles on village settlements, based upon his experience at Papworth; Herr Hans Wurtz offers a notable contribution to the education of the cripple, dealing largely with his mental rehabilitation and social adjustment; and the editor, Mr. Frederick Watson, discusses "Education for prevention of disease." A considerable amount of space is devoted to the training of cripples, with a survey of the present position in England, Germany, and Denmark, and notes on particular problems and on the work of various institutions.

THE FUTURE OF LOCAL GOVERNMENT IN LONDON.

THE London Council of Social Service in 1925 appointed a public health and public assistance committee to consider the proposed changes in local government which have now been embodied in the Local Government Bill, 1928, now before Parliament. This committee, which contained a majority of medical members, and had as its chairman Sir Arthur Newsholme, prepared a preliminary report early in 1926, and on the formulation of the Government's scheme last year resumed its consideration of the measures proposed, dividing this work between two subcommittees, dealing with public health and public assistance respectively. The views of the committee, which have now been published in pamphlet form,[1] deserve the attention of all who are concerned with the problems arising in the application of the Local Government Bill to London. This publication, indeed, should prove interesting to many who are not even remotely concerned with affairs in London, for it provides in summary form a suggestive study of the current tendencies in local government in general. The committee's observations on the actual provisions of the bill are of interest, but remembering the progress which the measure has already made in Parliament under a timetable, and that it appears likely to become law without substantial amendment, we may confine ourselves to the

[1] London Council of Social Service, 1, Express Mansions, N.W.3 (price 6d.).

views expressed upon the future development of local government in London. It will be remembered that the bill requires the London County Council—in common with other authorities of equal status—to prepare a scheme of administration providing for the discharge of its new duties. The committee calls for a realistic study of the question, remarking: "It is incumbent upon Londoners to consider according to each man's measure of experience and imagination, not an ideal system of public health and public assistance, but a system as near to that as the confused disorder of local government with its accumulated friction, jealousies, ambitions, and aspirations may allow the County Council to achieve." It is suggested that opportunity should be taken to link the chief branches of local administration—those concerned with health, education, and public assistance—into one organic whole. Space does not permit us to elaborate this thesis, but it is significant to note that the committee favours a high degree of unification in health services. The staffing arrangements of the London Education Committee are held up as a model for all counties, and the view is expressed that those of the new Public Assistance Committee might gain a similar standing if they were widened to include the part-time services of borough medical officers, who until now have held isolated positions in which their spheres of work—especially in relation to school medical services on the one hand and maternity and child welfare on the other—have been cut off from the main stream of public health services in London. It is regarded as anomalous that vaccination should be transferred to the borough councils while the functions of the Metropolitan Asylums Board, "virtually the authority for the treatment of small-pox," should go to the County Council. The committee considers that the public health and public assistance committees should be constituted by the County Council on the lines of the existing Education Committee, with a minority of co-opted members appointed by the Council on the nomination of social workers. Reference is made to the great amount of work done by voluntary associations, often administered by representatives of professional and other organizations of the type of the British Medical Association, and it is suggested that nominations might be received from such bodies. The medical subcommittee which discussed the bill welcomes the provision permitting the unification of health and assistance services under one authority, and regards as essential to the full realization of the reforms the reference by the County Council to its Public Health Committee of all medical functions transferred from the guardians. It is thought, however, that the grants for maternity and child welfare, for tuberculosis, and for venereal diseases should remain on a percentage basis instead of being replaced by the block grant. Great importance is attached to the assimilation under unified but decentralized arrangements of the various health officials now employed, and to the co-ordination of their work with that of the voluntary agencies, while the need for co-operation with the private practitioner is emphasized.

THE JOURNAL OF NUTRITION.

THE birth of new scientific journals, though often necessary, cannot be regarded as an unmixed blessing. Justification for specialized journals, like specialized departments, is found in the growing volume of scientific work; there is, however, the risk that an increase in output may be accompanied by a decline in the standard of work published. It is already difficult enough for those engaged in research work to maintain effective touch with recent developments in even one branch of scientific activity, and the publication of large amounts of indifferent work would make their task impossible. We may none the less welcome the appearance of the *Journal of Nutrition*,[1] a bi-monthly periodical published for the American Institute of Nutrition. Nutritional problems excite even more interest in the United States than they do in Europe, and clearly the journals devoted more generally to biochemical research are in danger of becoming overburdened. These problems, too, require somewhat specialized technique, and some of them are not necessarily of immediate interest to any but a rather limited group of workers. And finally, the names of Professors Lusk, McCallum, Dubois, and Mendel on the editorial board of the new journal should assure us that it will prove a valuable medium for the publication of original research work. On all these counts the *Journal of Nutrition* may be regarded as fulfilling an important need. The first number contains papers by several prominent American workers in the field of dietetics, and is noteworthy for its editorial review.

AN OPHTHALMOLOGICAL SERVICE.

WE publish in the *Supplement* this week at page 29 an article describing the provision of ophthalmic treatment on the clinic system, in accordance with a scheme drawn up jointly by the British Medical Association and the Association of Dispensing Opticians. This scheme is intended to give insured persons, their dependants, and others of a like economic status certain definite advantages not hitherto enjoyed by them. The underlying principle, stated briefly, is to ensure that such persons may have their eyes examined and spectacles supplied at a moderate cost. In this way the British Medical Association is endeavouring to fulfil the undertaking it gave last year to a Departmental Committee to arrange for an adequate ophthalmic service all through the country on terms which people of limited means can afford.

WE regret to announce the death, on January 27th, in his eighty-second year, of Dr. F. de Havilland Hall, consulting physician to the Westminster Hospital; an obituary notice will appear in our next issue. We have also to record the death, on January 28th, at the age of 65, of Mr. Victor G. Plarr, M.A., librarian of the Royal College of Surgeons of England, who was a valued occasional contributor to our columns.

THE KING'S ILLNESS.

WE learn on the best authority that His Majesty during the past few days has continued to make slow but steady progress towards convalescence, and that nothing has intervened to disturb the provisional plans for his removal to Bognor in the near future. Recent bacteriological tests confirm the clinical evidence that the right chest is now free from infection. The temperature has settled down, the pulse remains quiet, sleep is better, and solid food can be taken in larger amounts. Thus the gratifying improvement recorded last week has been maintained, and we may look for further news, from time to time, of advances along the uphill road to recovery. The profession and the nursing profession have every right to feel proud of the success so far achieved by those to whom the care of the King's life and health has been entrusted. Their skill and devotion, under wise leadership, have had full scope throughout, and for this the nation owes a great debt to the Queen, whose courage has been an example to her people. It was fitting that the first public message from the King since he fell ill should have been given by His Majesty at a hospital gathering: "His illness has brought him to appreciate more deeply than ever before the value of medical science and of devoted nursing."

MEDICAL EDUCATION OF WOMEN.

REPORT OF THE UNIVERSITY OF LONDON COMMITTEE.

THE report of the committee appointed by the Senate of the University of London in March last year "to consider the question of the limitations placed upon the medical education of women undergraduates and to report . . . thereon" was presented to the Senate in private last week and published on Saturday. The committee pronounced itself unable to find any valid argument, on the merits of the question, against the provision of co-education in medicine, which was regarded as the main point at issue, but emphasized the view that co-education to succeed must be voluntary. It recommended that copies of the report be forwarded to the schools in the Faculty of Medicine, and that the schools be invited, where they do not now do so, to consider the possibility of admitting a quota of women students. The Senate has given its general approval to the report, which does not bind that body to every word in it, and has accepted the tentative course of action proposed. A secondary point which may be indicated at this stage is that the question at issue relates to facilities for clinical education; the report reviews the nature of the medical curriculum as a whole, and points out that the facilities for pre-clinical instruction of women are ample, adding, however, that the fact that there may be difficulty in finding clinical facilities at a later stage must inevitably affect the number of entrants for pre-clinical courses.

Composition of the Committee.

The committee consisted of persons representing a wide range of interests. The then Vice-Chancellor, Sir William Beveridge, and the Chairman of Convocation, Professor Loney, were members *ex officio*, the remaining members being Dr. Graham Little, M.P., chairman of the Council for External Students, Sir Holburt Waring, F.R.C.S., chairman of the Finance Committee, Dr. Halliday, principal of King's College, Dr. Matthews, dean of King's College, Mr. Walter Spencer, F.R.C.S., vice-president of Westminster Hospital, Miss Strudwick, principal of St. Paul's School for Girls, Sir Andrew Taylor, representing University College, and Miss Tuke, principal of Bedford College. Sir Gregory Foster, principal of University College, and now Vice-Chancellor of the University, was afterwards added. Sir William Beveridge was chairman of the committee throughout its existence. Eleven meetings were held, at some of which representatives of certain medical schools and of other bodies, including the Medical Women's Federation, were interviewed. The chairman of the committee also attended a meeting consisting of representatives of all the medical schools. Much statistical information was supplied by the schools and by bodies such as the General Medical Council and the University Grants Committee.

After outlining the nature of the medical curriculum, as mentioned above, the report surveys the facilities for medical education in London and presents a review of the changing character of the extent to which the various institutions have admitted women students, which may be summarized as follows:

Of the twelve medical schools in London affording clinical instruction, none, before the war, admitted women, except the London School of Medicine for Women (Royal Free Hospital), which was founded for women only, and remains restricted to women. In 1916 St. Mary's Hospital, St. George's Hospital, and Charing Cross Hospital undertook to receive women for clinical studies. In 1917 Westminster Hospital, and in 1918 the London Hospital, King's College Hospital, and University College Hospital resolved to admit women, the last hospital named restricting the number to twelve a year in 1921. In 1919 St. George's Hospital, in 1921 the London Hospital, and in 1923 St. Mary's Hospital decided to admit no more women students. In 1928 Charing Cross, Westminster, and King's College Hospitals announced their intention of discontinuing the admission of women students in the future.

By July, 1918, of the twelve schools, four (the larger institutions) were confined to men, one was confined to women, and seven were open to both sexes. The effect of recent changes of policy is that there are now two schools only which offer clinical facilities to women—the London School of Medicine for Women, and University College Hospital Medical School which admits twelve women a year.

An Earlier Inquiry.

Reference is then made to the proceedings of a subcommittee of the Academic Council which was appointed in December, 1915, to consider whether the then existing facilities for the medical education of women in London were adequate, and, if not adequate, to suggest what means should be adopted to extend them. The members of this subcommittee in their report, formulated after prolonged consideration and discussion with the parties interested, expressed the following opinion on the general question before them:

"We are of opinion that no valid objection can be maintained against the system of co-education for men and women medical students; and that this is the only system by which the general policy of the university can be effectively carried out. In our opinion adequate facilities for the medical education of women would not be provided in any hospital or medical school unless resident medical and surgical appointments were open to men and women on equal terms."

The report was transmitted by the Academic Council to the Senate, and subsequently communicated to the medical schools. As a result a conference with representatives of the schools was held in January, 1917, when a considerable divergence of opinion was disclosed; on receiving the report of this conference the Senate decided to abstain from taking action in the matter. In the meantime, the opening of various schools to women during the war had for the time being relieved the situation. When the question again rose in 1921 on the decision of the London Hospital Medical College to restrict admission to men, another subcommittee of the Academic Council expressed the view that there was no lack of clinical facilities for women, and that no further action was advisable.

The Question of Numbers.

Having thus surveyed the question in its historical aspects, the report proceeds to the examination of the nature of the problem before it. Two aspects are recognized—that of providing clinical facilities adequate for the number of women requiring them, and that of providing such facilities in schools open to both sexes.

"In its first aspect," the report states, "the problem is a comparatively simple one. The great increase during the war in the number of women taking up medical studies has been followed by a striking decrease. On the evidence of Part II of the Second Medical Examination, as marking the passage from pre-clinical to clinical studies, in 1918 the number of women in London substantially exceeded that of the men; in 1919 the numbers were practically equal; from 1920, whereas men have maintained or increased their numbers, the women have fallen to less than a half. In the London School of Medicine for Women the total number of students, from 193 just before the war, rose to 459 in 1920-21 and fell to 293 in 1926-27. Outside London the fall in the numbers of women medical students has been even more marked."

The committee thinks it would be unwise to assume, however, that the figures of women entrants will remain at their present low level.

"There appear to be already indications of a revival," the report continues, "and though the policy of exclusion may for a time result in a number of women seeking admission to medical schools in the provinces and elsewhere, they will not, and in our view they should not, consent to being excluded from participation in medical education in the metropolis."

The committee is of the opinion that, taking all things into consideration, the provision of a hundred clinical places for women, apart from those available at the London

School of Medicine for Women, would be ample for the next few years. It holds, however, that the numerical side of the problem is the least important one. The real issue is as to the maintenance in London on a substantial scale of facilities for medical co-education at the clinical stage. The committee states:

"In all its other large faculties—for example, in Arts, Science, Economics, Laws—the University of London is predominantly co-educational; actually, though it has a few colleges confined to women, it has none in these faculties confined to men. The prepossession of the University of London has on more than one occasion been expressed to be in favour of a measure of co-education also in the great Faculty of Medicine," and asks: "Is there any feature peculiar to medical studies making co-education, which predominates in the rest of the university, undesirable in that one field?"

Objections to Co-education.

The report proceeds:

"We can say at once that we are satisfied that the relationship existing between men and women students of medicine is *not* of itself an objection to co-education, and we are glad to say that none of the representatives of schools who had had actual experience of women students alleged any case of difficulty or the need of disciplinary action arising out of this relation; uniformly the conduct of the women was described as excellent.

"In this respect our own conclusions agree with those arrived at by the inspector appointed by the Senate, the late Dr. J. George Adami, in his report on the medical schools. The report stated: 'The reports of the deans of the co-education schools regarding the work and attitude of the women students were uniformly favourable. The dean of one school bore evidence to the improved tone of the men students since women were admitted. The deans of two schools gave it as their impression that as the result of co-education the women students of their schools were more womanly and more considerate in their dealings with hospital patients than women trained apart from men.'"

The committee examined objections taken to co-education—such as the necessity for providing special accommodation (residential and other) for a mixed staff; the difficulty of teaching mixed classes in some subjects; the tendency of women to crowd to the front at demonstrations; and the difficulty in the way of reproving a person of one sex in the presence of persons of the opposite sex—and concluded:

"We think there must be some force in these objections, but . . . they have not been felt to be insuperable by schools with actual experience of co-education, and in fact they appear to us capable of adjustment with no more difficulty than most co-educational problems.

"Nor," the report continues, "are we impressed by the argument that the medical education of women is to a great extent thrown away by the 'wastage' that occurs, owing to marriage and other reasons which result in women leaving the medical profession after undergoing the expense and difficulty of qualification. As a matter of fact, it would appear from the information before us that the 'wastage' is much less considerable than is sometimes supposed. In so far as it has any weight, the argument tells not against co-education in medicine, but against any medical education of women at all. In London it certainly cannot be used as an argument for curtailing the facilities for women, for, in the aggregate, the number of places vacant is certainly greater than the number of applicants who could fill them.

"On the other hand, we think it is clear that in medicine women certainly gain by being educated side by side with men, and that such an education is a very valuable training for that co-operation which in their subsequent careers becomes necessary between medical men and women. It may be that the advantage is not felt so much by men students, and indeed co-education for some men may not be profitable. On the balance, however, we think that the advantage to the women outweighs any possible loss to the men."

Competition Among Medical Schools.

"We do not suggest, however, that there are no difficulties in the way of medical co-education in London. They are not the difficulties we have already referred to. The real difficulties arise from (*a*) the multiplicity of medical schools and their competition for students, and (*b*) the feeling against co-education entertained by some of the men already in the medical profession, some of the men students, and a section of the public. With few exceptions the authorities of the medical schools appear to be convinced that men, if they have a choice, prefer to go to schools which do not admit women, and that the feeling is strongest among the men, and in some cases the parents of the men, who on general grounds would be most desirable. Since there are now certainly not enough students to fill all the schools, this means, if some schools admit while others exclude women, that co-education is in unstable equilibrium; and that the school which admits any women will have a disappearing number of men.

"This feeling of antipathy may be deplored, but we have no doubt as to its existence, and since the medical schools are dependent to a very considerable extent on the income derived from students' fees, it is only natural that the authorities of the schools should be concerned with the economic problem to which it gives rise. In one of the cases at least in which a genuine attempt was made to provide absolutely fair treatment to women students, it was only the apprehension that the policy of co-education was heading the school for disaster which led to its reversal. How the exclusion of women can in all cases increase the number of men entrants all round is not obvious, for the number of possible entrants is not unlimited; that, however, is a matter on which we need not express an opinion. How long this feeling is likely to endure, and, in particular, whether it would endure indefinitely against the attraction of first-rate teaching and equipment in a co-educational school, are questions which it is difficult to answer."

Conclusions.

In their conclusions the members of the committee state that they are unable to see any valid argument against the provision of co-education in medicine, and that the prepossession of the university is in favour of such co-education.

"The changed public position of women in the past generation," their report proceeds, "is too obvious to need comment. If the field were clear we find it hard to believe that anyone who at the present day was planning afresh medical education in London as a whole would plan it otherwise than on the basis of being, like education in the other faculties, predominantly co-educational. In medicine, as in other fields of study, the services of the schools of the highest prestige and the teachers of the highest distinction should be available to men and women indifferently, and men and women who after their university careers have to work together in so many new relations should learn to do so at the university stage.

"We do not, indeed, wish to suggest that co-education should be universal in the medical schools. Among the consequences which might result from the adoption of such a policy would be that in some schools there would be only a very small number of women—perhaps only one woman. Such a condition of affairs would on various grounds be highly undesirable. There should, in our view, be three types of clinical education: (1) For men only; (2) for women only; and (3) for men and women. This involves the maintenance as men's schools of certain existing schools, the maintenance of at least one women's school, such as the London School of Medicine, and the provision of facilities for co-education."

The report takes cognizance, however, of the fact that the existing medical schools came into existence before the university; it is pointed out that some of them have long traditions to which they are naturally strongly attached, and that, having generally originated in the hospital with which they are associated and not having as a rule a separate legal existence, they are even more independent of the university than other schools. Further, a large proportion of their students are working for examinations other than those of the university. It is stated that at present the sole power which the Senate can exercise is to discontinue the recognition of a school as a school of the university, a power which has never been enforced. Under the new statutes, however, the Treasury grant from the University Grants Committee, at present paid direct to the medical schools, will be paid in a lump sum to the university. The committee does not consider that power over grants could or should be used to compel a medical school to remain or to become co-educational against its will. The report concludes:

"Co-education, if it is to succeed, must be voluntary. Where the war the tradition or policy of the medical schools was opposed to co-education, and its introduction during the war was due to the initiative of the schools, though it was welcomed by the university as being in accordance with its own policy. Its restoration can, we are convinced, only come about by an agreement between the university and the schools, and possibly by an arrangement by which the several schools would agree to a certain quota of women students."

Scotland.

Influenza in Scotland.

REFERENCE was made in this column last week to the recent outbreak of influenza and pneumonia in Scotland. The Registrar-General for Scotland reports that during the week ended January 19th deaths from influenza numbered 179, which was 123 more than in the previous week. Of these 179 deaths 151 occurred in Glasgow. The hospital accommodation in that city was greatly strained in dealing with cases of pneumonia, of which 640 were under treatment in the various hospitals of the city at the close of the week. To relieve to some extent a waiting list of 150 patients suffering from this disease a ward had to be specially set aside. The public services suffered severely, for about 250 tramwaymen were off duty largely from this cause, and the police force was reduced by a sick list of 230. In many schools, also, the proportion of absentees amounted to about one-half of the children. In Edinburgh the number of cases of influenza, though it was generally of a mild type, was very large. As a precautionary measure the staffs of the various hospitals received preventive inoculations. An offer was made by the health department of the city to inoculate the staffs of the tramway and other transport services, and this offer was accepted by a large number of the men, over 100 tramway workers having been inoculated by January 25th. In Aberdeen the outbreak has been milder; during December 42 cases of pneumonia were notified to the public health department, and in the first three weeks of January there were respectively 15, 18, and 29 such notifications. Up to January 25th the epidemic in Aberdeen, though of a mild form, had affected the city constabulary, tramway, bus, and post office staffs, as well as those of private offices, to a very considerable extent.

Edinburgh Royal Infirmary.

The committee appointed by the court of contributors of Edinburgh Royal Infirmary to consider the report of the managers (to which reference was made in the *British Medical Journal* of January 12th, at page 80) has drawn attention to several important points in connexion with the management of this hospital. It is pointed out that nearly 20,000 patients were treated in the wards in the past year, and that the number is steadily increasing. Of the cases admitted, 4,526 were medical and 14,466 surgical, whereas twenty years ago the relative figures were 4,104 medical and 6,828 surgical. At that time the average duration of a patient's stay in the Infirmary was 26.4 days, while last year the figure stood at 16.39 days; for surgical cases the average residence was reduced in this period from 23.4 days to 13.46 days. The number of patients from the country outside Edinburgh shows a marked increase; in 1908 patients admitted from the city numbered 6,259, and others 4,716, while in 1928 those from the city numbered 8,815, and from the country 9,964. Attention is drawn to the fact that, while the total number of hospital beds is 1,006, the waiting list on December 31st, 1928, comprised 2,692 cases. It is hoped that during the next year some relief will be gained by the recent addition of two small wards, and by the opening of the Astley Ainslie Institution, which up to the present time has had only 34 beds for female patients. The fund for extension purposes now stands at approximately £21,000, and within the next few years the neighbouring grounds of George Watson's College are to be taken over by the Infirmary. No definite scheme for utilization of this extra space has yet been prepared, but the question of providing accommodation for maternity cases and of building centralized quarters for the nursing staff is receiving consideration. It was also mentioned that the hospital's radium supply had been increased recently by a purchase amounting to £1,646, and that great developments in the treatment of cases by this curative agency might be anticipated from the managers' recent proposal for the establishment of a radium centre in connexion with the Infirmary. The committee made a special appeal for extended support to commemorate the foundation of the hospital two hundred years ago, and to mark the fact that the present year is also the jubilee of the opening of the buildings now in use. In connexion with the proposal for a radium institute under the management of the Royal Infirmary, which was outlined in the *Journal* of January 5th (p. 36), a sum of £5,000 has been offered to the board of management. It is understood that the gift is from two persons who desire to remain anonymous, and who have been induced to make this offer in memory of the spirit of devotion to the interests of suffering humanity exhibited by the two young doctors in London who recently sacrificed their health by overwork, which ultimately led to their tragic breakdown and suicide.

Edinburgh Medical Missionary Society.

The annual general meeting of the Edinburgh Medical Missionary Society was held on January 24th at 117, George Street, Edinburgh, with Mr. C. W. Catheart, F.R.C.S., in the chair. The financial statement showed that without any abnormal increase of income the year's expenditure had practically been met. Two years ago there was a deficit of £1,422; this was subsequently reduced to £725, and at the end of the year under review the debt to be carried forward was only £67. The usual medical and social work was carried on in the Cowgate district by students and volunteer helpers, and the hospitals of the society abroad had a busy and satisfactory year. The resignation from the post of superintendent and secretary of Dr. Lechmere Taylor was intimated, and Dr. F. O. Lasbrey, superintendent of the Cairo Medical Mission and secretary of the Church Missionary Society in Egypt and the Upper Sudan, was appointed to succeed him. Dr. Taylor, in submitting a survey of his work, said that the society existed for the fundamental object of training men and women for medical missionary service in different parts of the world. He had made an examination of the positions now held by the 79 medical students who had passed through the hands of the society, and he had found that only a very small number of them were not now in active missionary service. A few had fallen out for reasons of health, or of family considerations, but he thought that the great success in training which had been accomplished merited a continued public support of the society's work. The adoption of the report was moved by the Rev. Dr. R. Laws of Livingstonia.

England and Wales.

New Operating Theatres at Leicester Royal Infirmary.

Two new operating theatres, with accessory rooms, equipped on the most modern lines, were opened on January 23rd at Leicester Royal Infirmary by Mr. C. J. Bond, F.R.C.S., consulting surgeon to that institution; his connexion with it has extended over a period of more than fifty years. In the course of the ceremony Mr. Bond briefly reviewed the development of surgical work in the Infirmary. He described a small room in the old central building, with a double door to admit stretchers, a flat skylight in the ceiling, an open fireplace, and candles or gas for light; on one side were some wash-hand basins and, in an adjoining room, a cupboard for instruments, and a row of blood-stained dirty overcoats. It was in this room, he said, that in 1875, when he started as a pupil, and in 1882, when he became house-surgeon, all the more important operations were performed. Mr. Bond recalled the crude apparatus employed in this work and the difficulties which faced the surgeon at that time, and mentioned the introduction of antiseptic surgery and of improvements in inducing anaesthesia. As house-surgeon and the only qualified resident officer he had had charge of both surgical and medical wards, including thirty typhoid beds; he dealt with casualty and emergency cases, and helped with the out-patients; he performed post-mortem examinations, and attended inquests and board meetings; and he operated in emergencies in the absence of the surgeon. The speaker recalled the opening of the modern theatres in the Victoria wing of the Infirmary in 1902, and of the important work since carried on in them, and discussed the value of the most recent addition to the institution's resources. Finally, in speaking of the future of surgery and its relation to other forms of treatment such as

radiology, he remarked that something more was required of a surgeon nowadays than mere manual skill; he must possess surgical insight and be able to appreciate what was going on in the patient's system; he must know when to operate and when to refrain; he must understand the natural and physiological methods of defence and be able to reinforce them when necessary.

Transference of Queen Charlotte's Hospital to a New Site.

The Management Committee of Queen Charlotte's Maternity Hospital has announced that the entire hospital, with the nurses' home and post-graduate and students' college, is to be transferred from the present "cramped, noisy, and unsuitable" site in Marylebone Road to a quieter part of London. Negotiations for a suitable situation are in progress, and plans have been prepared for the erection of a new hospital on the most modern lines. It was felt that in its present position the work of the institution could not be adequately developed, and the policy of removal, which has the approval of the Ministry of Health and of King Edward's Hospital Fund, was accordingly adopted. In the course of an official statement which has been issued mention is made of several features of the proposed scheme. The plans provide for the erection of an isolation block for cases of puerperal fever; this, it is believed, will be the first of its kind in this country in a voluntary hospital. Special provision will also be made for research work on puerperal fever, as part of the campaign against the high maternal mortality from it. It may be recalled that such preventive work was foreshadowed nearly two years ago, when an appeal for £250,000 was made by the governing body of the hospital; some comment on it appeared in our columns on May 7th, 1927 (p. 851). Another block in the new building will be reserved for pre-natal cases, which have hitherto suffered from the almost general lack of provision for their particular needs. It is also proposed to set apart a considerable amount of accommodation in the form of comfortable bedrooms for paying patients of moderate means; this provision will be on as large a scale as possible, and will not be regarded merely as an unimportant adjunct to the charity work of the institution. It is believed that this development will do much to encourage the desirable practice in London of providing such accommodation on an equal scale both for the poorer classes and for people of moderate means. The importance of this rests upon the belief that no single movement will do so much to diminish maternal mortality as the reception in hospitals of maternity cases from all classes of the community, because mortality is equally high among rich and poor. The new hospital will be constructed as a number of units, and it is thought that the first of these, the isolation block, may be completed by the spring of next year. Ample room for future expansion will be available.

Middlesex Hospital New Nurses' Home.

The Queen, on January 24th, laid the foundation stone of the new nurses' home of the Middlesex Hospital, which is being erected in Foley Street, on a site adjoining the hospital. When completed the home will provide sleeping, refectory, and recreation accommodation for 450 sisters, nurses, and maids; its construction has been made possible by the generosity of an anonymous donor, who has given £200,000 to the hospital. In the course of the proceedings a message from the King was conveyed by the Queen to Prince Arthur of Connaught to the effect that His Majesty was very pleased that the Queen was laying the foundation stone of the new nurses' home. His illness, it was added, had brought him to appreciate more deeply than ever before the value of medical service and of devoted nursing. Prince Arthur in his speech referred to the Queen's interest in the welfare of the voluntary hospitals and their staffs. At the close of the ceremony Her Majesty visited a number of the wards of the hospital. The Middlesex Hospital motto is *Miseris succurrere disco*, and a new significance attaches to this Virgilian phrase when it is recalled that the whole sentence, which was part of Queen Dido's address to the afflicted Aeneas and his followers, runs: *Non ignara mali, miseris succurrere disco*; this may be rendered, "Not unacquainted myself with trouble, I learn to aid the afflicted.

Correspondence.

TREATMENT OF NON-SPECIFIC DIARRHOEA IN THE TROPICS.

SIR,—In a short article on November 10th, 1928 (p. 843), Dr. C. V. Thornton divides tropical diarrhoea into two main groups. In the first, when a specific cause is demonstrable, he only mentions (1) the dysenteries (which, I presume, are meant to cover amoebic dysentery, the various forms of bacillary dysentery, and probably hill diarrhoea); (2) sprue; (3) tuberculosis; and (4) syphilis. To these, at the end of his article, he adds cholera and food poisoning; he might have included typhoid and paratyphoid fevers. His second group contains diarrhoea not caused by any of these agents.

After working five years in Assam and two years in the Seychelles Islands I feel safe enough in stating that there are comparatively few cases of diarrhoea in the tropics to which definite causes cannot be assigned.

In Assam the condition that gave us most concern was "choleraic diarrhoea," a form of very acute gastro-enteritis which closely resembles cholera clinically, but which is definitely not cholera; it is considered by us as merely a syndrome or set of symptoms common to several diseases of absolutely different agency. After four years' work among tea-garden coolies in Assam we were eventually able to arrange those cases of choleraic diarrhoea in five main groups: (1) cases of acute bacillary dysentery; (2) cases of algid subtertian malaria; (3) cases of mushroom poisoning; (4) cases of food poisoning; (5) cases to which, in the absence of detailed laboratory investigation, no definite cause could be assigned. Preliminary notes by me on the etiology and diagnosis of choleraic diarrhoea were published in the proceedings of the Assam Branch, British Medical Association, 1926.

But apart from choleraic diarrhoea and diarrhoeas due to the specific causes mentioned by Dr. Thornton, may I suggest (seeing that he does not mention them under specific diarrhoeas) that he may have overlooked diarrhoeas caused by intestinal protozoa other than the *Entamoeba histolytica*, and also diarrhoeas caused by certain helminths. While there may even be other such parasites which I have personally not met with, in my experience the following parasites are often responsible for diarrhoea in the tropics: (1) *Balantidium coli*; (2) *Entamoeba coli*; (3) *Giardia intestinalis*; (4) *Trichomonas hominis*; (5) *Chilomastix mesnili*; (6) *Blastocystis hominis* (a vegetable parasite); (7) *Strongyloides stercoralis*; (8) even ascaris, ankylostoma, and trichiurus, are liable to cause more or less protracted diarrhoeas in children, and in looking for finer causes the presence of these may not be realized. In quite a large number of cases of diarrhoea, varying in degree of severity and in duration, these parasites are invariably found, either singly or associated two or more in the same case.

In the case of protozoal parasites, including *Blastocystis hominis*, stovarsol, in my hands, has proved a specific, and even in the cases of diarrhoea of unknown causation I suggest that stovarsol is worth a trial. Special mention must be made of *Balantidium coli* and *Strongyloides stercoralis* as agents of protracted diarrhoea. Human balantidiosis is much more common than hitherto realized; it may be responsible for diarrhoea lasting for years and eventually proving fatal. From Assam I reported three cases only discovered towards the end of my time there, and here in Seychelles I have in two years had thirty-five cases under my care. These cases I may state are reported for the first time from these islands, so far as I am aware. In all these cases (one actually of about five years' duration) stovarsol has established a definite cure without relapse after an average course of six days' treatment with it.

Strongyloides stercoralis causes very often a protracted form of diarrhoea, the patient sometimes having as many as fifteen stools in twenty-four hours. It is a parasite extremely difficult to expel, requiring repeated treatment with chenopodium and carbon tetrachloride combined. In their eventual removal invariably puts an end to the diarrhoea.

The liver treatment advised by Dr. Thornton is very interesting, but if the help of the microscope is constantly sought and carefully applied to the investigation of diarrhoeic stools, the application of liver therapy must necessarily become very restricted.—I am, etc.,

L. C. D. HERMITTE, M.B., Ch.B., D.T.M. and H.

Mahe, Seychelles Islands, Dec. 28th, 1928.

PYORRHOEA ALVEOLARIS.

SIR,—In the kind notice you bestowed in your leading article on my remarks about pyorrhoea alveolaris (January 19th, p. 115) you appeared to invite discussion on some points of detail which lack of space compelled me to omit or to treat somewhat briefly in my paper. I certainly recognize the wide difference that separates the soft yellow calculus (liable in many mouths to be deposited from the saliva on all hard surfaces, whether teeth or artificial dentures, which are not cleansed by friction), and the harder, darker, subgingival calculus which is, I believe, the causative agent in pyorrhoea; though obviously the former, by encouraging stagnation, will facilitate the deposit of the latter. But I believe that to regard the blood serum as the sole source of subgingival calculus (it is often styled serumal calculus) is going further than our present knowledge warrants. I therefore used the general term "oral secretion" to cover not only saliva, but mucus and serum as well. Saliva contains mucus, and would appear to be sufficiently viscid to stagnate in the interdental spaces. The point is still *sub judice*, and is not, after all, of great importance.

It is annoying to have the two terms tartar and calculus in common use, but as popular and professional custom appears to regard the two as interchangeable, I have not attempted to distinguish between them.—I am, etc.,

H. F. HUMPHREYS.

Birmingham, Jan. 22nd.

SIR,—In his letter (January 26th, p. 176) Mr. Bertwistle, referring to Mr. Humphreys's article on the above subject, states "I fully endorse his opinion that a negative radiogram means nothing, though a positive one is invaluable. Weston Price goes further, and states that it is just those teeth which present no radiographic evidence of disease which are the worst offenders." I venture to suggest that Mr. Bertwistle has misrepresented the opinions of both these authors. Apart from acute lesions, which are producing symptoms and can usually be detected by a clinical examination, I maintain that the negative evidence in those cases where a clinical examination is negative is most valuable, and that it is rare for the radiographic evidence of teeth producing systemic disease to be negative.

Weston Price estimates that about 10 per cent. of teeth which are septic show no change on the radiograph, but several of the radiographic illustrations he uses to demonstrate this point show definite lesions. On the other hand, radiologists find apical abscesses, sometimes of considerable size,[1] every day in patients complaining of symptoms, attributed by their medical advisers to dental sepsis, whose teeth have been very carefully examined by skilful dental surgeons with negative results.

To my mind the important feature is not the relatively rare case of dental sepsis in which changes are absent to the clinical observer, and the lesion is not shown on the radiograph, but the failure of some dental surgeons to appreciate the danger of lesions which are very obviously shown on the radiograph, because no local clinical signs are present. Sometimes teeth, the radiographs of which show definite septic changes at the apices, are subsequently root-filled—a procedure which is both dangerous and unjustifiable. The excuse that the tooth is "useful" in any sense should not be considered. I have recorded[2] the grave results which have followed this procedure.

Similarly, the wholesale extraction of teeth without clinical or radiographic evidence of sepsis is to be condemned, and though of the opinion that all dead teeth are a potential source of danger to the patient, I hold that, even if a tooth has been root-filled, provided the clinical and radiographic evidence, as far as this tooth is concerned, is negative, it is purely empirical to extract this tooth.—I am, etc.,

JAMES F. BRAILSFORD, M.D.

CARDIOSPASM OR ACHALASIA OF THE CARDIA.

SIR,—Though not desiring to enter the lists in the discussion on the pathogenesis of oesophagectasia, I wish to record observations made in operating on three of these cases. Those who perform the operation of digital stretching of the cardiac orifice do not get the opportunity of observing either the relations of the abdominal oesophagus or the state of the musculature.

I have operated on three cases, referred to me by physicians, by the method described by Mr. R. P. Rowlands. (I do not know if he was the originator of the operation.) All three were well-marked cases, and two of them had received treatment for a considerable period with the mercury tube, which had in both cases become a necessity before each meal. The third case had had a shorter period of treatment, and was operated on only a few months ago.

The details of the operation are as follows: After medium laparotomy the cardiac end of the stomach is drawn down and the peritoneum divided round the oesophagus as it emerges from the diaphragm. A piece of rubber tubing is then passed behind the oesophagus and gentle traction employed. In this way it is quite easy to expose two inches or more of oesophagus. An oesophageal bougie is then passed down the gullet into the stomach, and the circular fibres of the terminal inch or so of the oesophagus are carefully divided right down to the cardiac end, both anteriorly and posteriorly. Great care is taken to avoid injury to the mucosa and to the vagi.

The operation is more simple than it sounds, and can be completed in about fifteen minutes. With regard to results: immediate relief of symptoms has followed operation and lasted for a variable time, but sooner or later symptoms have recurred, though less severe in character. This I believe to be often true after digital stretching. I do not know whether the late results of Walton's cases are as good as they were when he published his paper, but it would be of interest to hear.

In my three cases I can definitely state that at operation (1) there was no cardiospasm, a plain bougie passed quite easily—before anaesthesia only a mercury tube would pass; (2) there was no suggestion of sphincter hypertrophy, in fact no distinctive sphincter could be detected; (3) in all three cases, though varying in degree, there was a well-marked tongue of the Spigelian lobe of the liver lying immediately behind the lower end of the oesophagus.

My object in writing is to record these observed facts in three cases operated on. It would be foolish to attempt to draw conclusions from observations on three cases, but facts rather than theory are necessary to elucidate the problem. In the first case operated on the tongue of liver lying behind the gullet was very noticeable, and my attention was called to it by Mr. Douglas Harmer, who was present at the operation. In both the others there was a definite projection of liver substance, but not so marked as in the first case. That this unusual relationship can have any bearing on the cause of the disorder seems unlikely, but the coincidence is odd. It seems probable that during respiration the oesophagus below the crura becomes wedged to some extent into the V-shaped gap in the liver as the liver is squeezed by the piston-like descent of the diaphragm. It is mere conjecture to suggest that this may have some bearing on the disturbance of the vagi. I record the anatomical facts on the off-chance that it may help in the solution of the problem.

The other two observations seem to support the views held by Hurst. Dr. Hurst has been taken to task for his reference to postural tone, which Sherrington defined as "a reflex contraction excited by stretching." It seems to me that, whatever the cause of the degenerate changes in Auerbach's plexus, the clinical syndrome fits in with a disordered neuro-muscular mechanism and a disturbance of postural tone.

Sherrington called attention to the dual activity of muscle: the one concerned with movement, tonic activity, the other with posture; the one *phasic*, the other *tonic* (plastic tone), distinct physiological functions. This dual function will explain the deformity which results in joint disease, and the marked wasting which follows. Space will not permit a discussion on this theme, though there are some interesting points bearing on the subject under debate. If we accept as a universal factor the findings of Mr. G. W. Rake, we can accept not only the disturbance of the postural tone as described by Hurst, but also inhibition of the phasic tone which should give the stimulus to relax.—I am, etc.,

London, W., Jan. 25th. C. GORDON-WATSON.

SIR,—Mr. Greenwood, in his letter published on January 19th (p. 131), brings forward nothing in support of his contention that achalasia of the cardia is really due to spasm, which did not appear in his original article, to which I have already replied. Moreover, I have published the evidence in favour of the achalasia theory so fully in various places that no further answer is called for.

It is, however, necessary to deal with Mr. Greenwood's personal attacks. He suggests that I came to the conclusion that so-called cardiospasm was due to achalasia of the cardia on the strength of the single case I showed at the Royal Society of Medicine in January, 1915. If, however, he had taken the trouble to read my full paper on the subject published later in the same year, in the *Quarterly Journal of Medicine*, he would have seen that I had at that time investigated seven cases, and that I had waited for five years after the idea of achalasia first occurred to me in order to obtain sufficient evidence in its support before I published my observations.

Mr. Greenwood states that it was Sir Humphry Rolleston's conception of the pathology of so-called cardiospasm that suggested to Sir Cooper Perry the alternative nomenclature, and he accuses me of adopting both the explanation and the terminology without acknowledgement. If Mr. Greenwood has, as he states, consulted the extensive literature, he must know that he is making a false accusation. I have always acknowledged the priority of Sir Humphry Rolleston as the originator of the theory of achalasia, since he called my attention to his 1895 paper when I gave my views on the subject for the first time at the Royal Society of Medicine in December, 1914 (vide *Quart. Journ. Med.*, 1914–15, viii, 300; *Medical Essays and Addresses*, 1924, p. 110; *British Medical Journal*, January 24th, 1925; and *Lancet*, March 19th, 1927).

In my original communication on the subject at the Royal Society of Medicine I described how Sir Cooper Perry had coined the word achalasia in response to a request from me for a single word to express "absence of relaxation." In spite of Mr. Greenwood's suggestion of plagiarism on my part he must be aware of this, because Sir Cooper Perry has never written on the subject himself, the only references to his authorship of the word being in the papers I have myself written.

Dr. Beatty (January 26th, p. 179) still objects to the condition under discussion being regarded as a disease of the cardia. But the hypertrophied and dilated oesophagus is an essential part of the picture, and this occurs in achalasia of the cardia and not in spasm of other parts of the oesophagus. One speaks of carcinoma of the cardia and pylorus, although carcinoma occurs in other parts of the oesophagus and stomach; so why not achalasia of the cardia? Oesophagoscopy shows that most cases of spasm of the oesophagus are secondary to some small local lesions; the case of multiple stricture I referred to is the only one I have seen in which no such lesion was discovered.

I think that some of Dr. Beatty's *x*-ray observations may depend upon a fallacy which I only discovered after much investigation, and which is still ignored by most radiologists. The oesophagus is always full of non-opaque material in achalasia, unless the individual has recently vomited. Hence with an opaque meal, which slowly sinks to the bottom, one does not see the whole eight-inch column. The only satisfactory way to *x*-ray these cases is to empty the oesophagus by a Senoran's evacuator and then give a big enough meal—often a pint or a pint and a half—to fill the distended oesophagus afresh.

In referring to the safety valve of a boiler I meant the simple ball valve such as is used in toy steam engines. This closes by falling back when the pressure ceases to be excessive: cannot one picture a similar return to the normal postural tone of the sphincter when it is no longer forced open by excessive pressure? (I have not replied to Mr. Greenwood's references to postural tone because he is apparently ignorant of Sherrington's work on the subject, and thinks "postural tone" is another wicked invention of mine.)—I am, etc.,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Jan. 28th.

*** Owing to the heavy claims upon our correspondence columns we are unable to find space for further discussion of this subject.

ENLARGEMENT OF THE PROSTATE.

SIR,—I am interested in the article by Mr. C. A. R. Nitch on "Benign enlargement of the prostate" (January 26th, p. 139) because he apparently recommends the combination of two different operations of prostatectomy—namely, Freyer's operation and the operation that I described and have advocated for a number of years.

The essential points of Freyer's operation are enucleation with the finger through a small suprapubic incision while the abdominal wall is forced downwards with the knuckles to reach the prostate that is forced upwards by a finger in the rectum. The essential features of my operation are a long incision that allows the hand to sink between the recti and the finger to reach the prostate easily, thus obviating the use of the rectal finger and the full display of the bladder base by retractors and the Trendelenburg position in order to remove fragments of prostate, tags of capsule, and flaps of mucous membrane, to ensure a large opening between the bladder and prostatic cavity, and to control bleeding by ligature and suture.

At one part of his article Mr. Nitch recommends the Freyer operation, but qualifies this by saying that "if the walls [of the prostatic cavity] are uneven, and contain irregular masses of small adenomata, an open operation should be performed." Now it must have struck every surgeon who practises the method I described that the finger is not a reliable guide to the presence of semi-detached layers of capsule and flat portions of prostate in the wall of the prostatic cavity, and that inspection reveals quite unexpected irregularities. Moreover, these prostatic relics are only one source of post-operative obstruction and sepsis out of many that can be displayed by inspection and cannot be felt by the finger. The guide on which Mr. Nitch depends in deciding whether to convert a Freyer operation into what he calls an open operation is therefore unreliable.

At another part of the article Mr. Nitch would "emphasize the importance of a long incision in the abdominal wall" to allow free access to the prostate and to "dispense with the necessity for a finger in the rectum." This is no part of Freyer's operation, but it is an essential part of my operation, and one which I have reiterated in the medical press for many years. Mr. Nitch cannot have it both ways. He cannot have a finger in the rectum and avoid putting a finger in the rectum. What, then, does he really recommend? I confess that I am unable to decide.

I am gratified, nevertheless, that Mr. Nitch should have adopted, or at least approved of, even part of the technique that I have recommended so long and so often.—I am, etc.,

London, W.1, Jan. 28th. JOHN THOMSON-WALKER.

TONSIL AND ADENOID OPERATIONS.

SIR,—In the execution of an operation which all surgeons practising in this specialty are often called upon to perform there will naturally be variations of technique, and a wise forbearance should be exercised in the criticism of the methods of others. But are our results all that we could wish?

It would appear that amidst the cloud of controversy certain undeniable principles which we would all ad-

are in danger of being lost sight of. They are: (1) An absolutely safe anaesthetic. (2) Removal of the entire tonsil tissue—including the lingual tonsil. (3) Regard to the preservation of the anterior and posterior pillars, and a recognition of the powerful nerve reflex which any roughness to the tonsil would bring into play. (4) A minimum of haemorrhage at the time, and no after-bleeding at all.

In regard to the first point, is it not time that the "myth" of a persistent thymus as a cause of death be decently buried, and every case of death under anaesthetic be frankly investigated with an open mind, and the lesson laid to heart? For the surgeon bears his share of the blame with the anaesthetist.

In regard to the third point, I must join issue with my friend Dr. Horgan, when he says (January 12th, p. 84), "In a surgical operation the safety and efficacy of which is largely dependent upon the celerity with which it can be carried out. . . ." In my judgement neither safety nor efficiency is served by speed, but only convenience.

In regard to the fourth point, surely the danger of haemorrhage is rather under-estimated. Deaths from haemorrhage after this operation are reported in the coroners' courts all too frequently. Each one of these regrettable incidents not only reflects on the surgeon concerned, but affects the attitude of the public towards tonsil operations.

Do children stand loss of blood as well as we suppose? Are we sufficiently critical of the amount of blood our patients lose at the time of operation? If a child has a serious haemorrhage it will take nearly a year to get over its effects.

While we must feel indebted to Dr. Clarke (January 5th, p. 45) for calling attention to the disadvantages of ligaturing large bunches of tissue, I see no reason why the surgery of the tonsil should be denied the advantage of the time-honoured principle of surgical ligature of bleeding vessels. It may be difficult, it may require some skill and practice, but it makes for certainty, safety, and the surgeon's peace of mind. It is clearly the method of choice in the operation for adults.—I am, etc.,

Birmingham, Jan. 21st. MUSGRAVE WOODMAN.

SIR,—I was gratified to read in your issue of January 26th a letter from so able a pen as Dr. Dan McKenzie's expressing views anent the "let it rippers" in tonsil haemorrhage. I am in entire agreement with him, and like him have long since joined the almost maligned army of "haemostats."

In my earlier years I practised the dexterous art of as rapid a tonsillectomy as possible, regardless of coincidental haemorrhage. But a few "humiliating and uncomfortable" experiences, culminating in a chance remark once made by a doctor, woke me up to the realization of the adoption of general surgical principles, *even in tonsil operations*. The doctor whose case I had tonsillectomized, thirty miles away from Manchester, remarked "What shall I do for bleeding?" This set one thinking how uncertain was the technique.

It has always been a mystery to me why there should be this ruthless disregard for haemostasis, for I can recall no other surgical procedure where similar methods are adopted. In the past, the prevalent slogan appeared to be "Quick in, quick out, and quick out of the house," but one is happy in the belief that such is rapidly disappearing. Tonsillectomy after all is *an operation*, though I well remember, after giving a post-graduate lecture on this subject, a member of the audience remarking, "But you are making it a major operation."

Believing as I do that quite 95 per cent. of tonsils in all ages can be completely and expeditiously enucleated with the blunt guillotine, at least let us take time to ensure haemostasis in one tonsil bed before enucleating the second tonsil. This desideratum necessitates a longer anaesthesia than that induced by ethyl chloride or nitrous oxide, though need not, in the majority of cases, take more than five minutes.

Without wishing to reopen the question of anaesthesia in tonsillectomy, I consider that on occasion it may be one of the most difficult duties an anaesthetist undertakes, and calls forth all his skill, co-operation, and experience, which is such a comfort to the surgeon.—I am, etc.,

Manchester, Jan. 26th. F. HOLT DIGGLE.

SIR,—Many readers, especially those who are not laryngologists, must wonder at the conflicting opinions held by your correspondents. Why is it that some laryngologists remove tonsils solely by the dissection method, while others in the great majority of their cases use the guillotine method of enucleation? Why is it that some insist on routine ligaturing of vessels in the tonsil bed, while others say that they never, or shall we say hardly ever, have to tie a vessel? How can we reconcile the results of the ripe experience of Mr. Tilley with the remarkable results of Dr. Horgan?

The modern reverse method of using the guillotine was first advocated in 1910 by Whillis and Pybus of Newcastle. The method was adopted by Sluder in America, and came back to us with enhanced reputation as Sluder's technique. During the war little teaching was done, so it came about that the modern method of removing tonsils is practically a post-war change.

Enucleating tonsils with the guillotine is like hitting a golf ball. It looks quite easy, but is not so easy as it looks. A pedunculated ("tee'd up") tonsil may be quite easy, but to be sure of removing tonsils completely from a "buried lie" requires a great deal of practice—much more practice, in my opinion, than the dissection method. To become really expert one has to remove many hundreds of all types of tonsils, and one has, like golf, to keep in practice or the knack goes. Those whose lot it is to remove fifteen or twenty tonsils a week tend to adopt the guillotine. Those who have one or two tonsil cases sandwiched in their operation list tend to use the dissection method. They have in it a method which has served them well, a method which in good hands will produce the desired result, whereas the guillotine, like the golf club, is fickle, and the more you neglect it the less likely it is to produce a first-class result.

On reading through the letters it is noticeable that the "dissectionists" emphasize the danger of bleeding, and advocate routine tying of vessels. The "guillotinists" state that they rarely get bleeding, and tie vessels only when it is necessary. Does the method explain some of the divergence of opinion?

With the latest tonsil écraseur, described by Mr. T. B. Layton,[1] it is possible to remove tonsils without any bleeding whatever. It requires a more prolonged anaesthesia, of course, than ethyl chloride, as one has to wait the coagulation time of the blood of each tonsil, and its use has not displaced the ordinary guillotine where large numbers have to be dealt with. It occupies no longer time than an ordinary dissection, and it safeguards any damage to the anterior pillars, which is always a possibility with ordinary guillotine operations.—I am, etc.,

Guildford, Jan. 25th. T. B. JOBSON.

SIR,—The source of haemorrhage during and after the operation of enucleation of tonsils appears to be worthy of consideration. It seems to be largely accepted as being arterial in character.

Having performed at least 8,000 complete enucleation cases, under chloroform, I take this opportunity to state that I have rarely seen the smallest spurt from an artery; but, years ago, haemorrhage after operations occasionally caused me considerable anxiety. I found this to be due to the division of a fairly large vein (I have occasionally seen two running parallel). In these cases the vein extends the whole length of the tonsil bed, running vertically from above downwards. Its position is at about the junction of the posterior and middle thirds of the fossa, left after the removal of the tonsil, and is situated in the connective tissue of the capsule. During the operation the greater part of this vein appears to be usually excised, and it may bleed very freely from the extreme upper or lower ends of the wound.

[1] *Lancet*, December 15th, 1923.

I find that Spencer Wells's artery forceps applied to the bleeding point, at the time of operation, and allowed to remain on for five or ten minutes, yield most excellent results.—I am, etc.,

E. MALCOLM STOCKDALE.

Liverpool, Jan. 28th.

SIR,—The subject of the paper by Mr. Sandiford and Dr. Clayton (July 28th, 1928, p. 149) was the guillotine operation in children under ethyl chloride anaesthesia, and it was from this standpoint that my letter (December 15th, p. 1113) was written.

An essential factor in the modern guillotine operation is that manipulation with a blunt instrument arrests haemorrhage by tearing and twisting the outer coat of the vessels and causing the inner to contract and retract, thus attaining much the same result as by the use of a ligature. In operation by dissection, especially if scissors are used, ligation, as a rule, is necessary. The gauze pressure, to which I referred, is an extra precaution to control, not arteries, but capillaries which may have escaped the action of the guillotine.

In answer to Mr. Herbert Tilley's questions I would state that in my experience the anaesthetic and analgesic periods produced by ethyl chloride are sufficiently long to admit the application of efficient pressure and to deal with the exceptional vessel by ligature or stitch; indeed, Mr. Tilley answers his own question when he states in a subsequent part of his letter that "the time required for doing so will often be less than eight or ten seconds." Should the period, however, prove too short it is a simple matter to give a little ether, while keeping up pressure on the tonsil bed.

I would be the last to treat the subject of haemorrhage during any operation in a "light-hearted way," but surely Mr. Tilley misunderstands me. I wrote, and mean, "little." A little capillary bleeding, estimated by StClair Thomson to be about one ounce in the guillotine operation in children—in some cases I think it is less—is, I suggest, beneficial in cleansing what is usually a very septic area. If the bleeding is more than a little then the tonsil bed should be carefully examined, and should a definite bleeding artery be found it should, of course, be secured with a ligature, while if multiple bleeding capillaries are seen the pillars should be stitched. Such cases are, however, in my opinion, rare.

With regard to secondary haemorrhage, in a recent series of over three hundred cases, aged 1 to 14, the proportion was under 1 per cent., and in a former series even lower; in these cases the operation described in my former letter was done, and in none of them was it considered necessary to use ligature or stitch. The type of haemorrhage, fortunately rare in children, to cause real anxiety is the flood-like bleeding from a large number of vessels. This is met with in others than recognized haemophilics, though there is little doubt that the cause is a very low coagulation power of the blood. In such cases ligation is impossible and useless, while stitching of the pillars is not trustworthy, and is very difficult to carry out at once. They are, however, in my experience, invariably controlled by packing the tonsil socket with strips of gauze and exerting pressure and counter-pressure from outside for a minute or two, while 10 c.cm. of normal horse serum and 1/12 to 1/6 of a grain of morphine are injected. On careful removal of the packing the bleeding is found to be arrested and the pillars may now be stitched, though usually this is unnecessary. The bleeding, in a much modified degree, may recur in a few cases, when horse serum may be repeated, in two injections, if required, giving in all up to 30 c.cm.

H. NORMAN BARNETT.

Bath, Jan. 18th.

TREATMENT OF CANCER BY LEAD.

SIR,—In the *British Medical Journal* of January 12th (p. 82) Mr. Hume, referring to my letter published on January 5th (p. 42), says that I made certain statements about the St. Bartholomew's report that are so misleading as to call for correction. Let me then support my statements by facts culled from the original report of the St. Bartholomew's Hospital Cancer Committee on the observations of Mr. Hume and his fellow workers.

Fourteen out of a total number of twenty cases treated received less than 0.25 gram of lead, about half the minimum dosage recommended by us, unless, of course, a satisfactory result is obtained with a smaller dosage. Eight of these fourteen apparently received less than 0.2 gram. Of the six that received more than 0.25 gram, only one seems to have been given as much as 0.4 gram; not a single case was treated to the minimum full extent (see Table II, original report). If, then, my statement that the patients were too ill to receive more than a small quantity of lead was not justified, the only alternative explanation of the unsatisfactory results is that the work was not properly conducted. I shall show, however, that both factors were concerned in producing the bad results.

I complained that a series of only twenty cases was quite inadequate. Mr. Hume asserts that this small number should have been "sufficient to estimate the likelihood of the method being of practical value." Yet in the original report we find the lament that "It is regrettable that so few cases were available for investigation." I would draw attention to the explanation in this report of the paucity of cases treated. "After June" (that is, after only four months' work, a period too short for the satisfactory treatment of any one patient) "there was a very pronounced falling off in the number of cases . . . partly due to a shortage of beds . . . but also to the fact that the staff of the hospital had by that date formed so unfavourable an opinion of the treatment that they were unwilling to submit their patients to it." I cannot believe that any committee of scientific men would regard that period of time and that number of cases as sufficient to enable them to decide a matter so important as that under investigation.

In his conclusions Mr. Hume states that the average duration of life subsequent to treatment was only thirteen weeks, and seeks to throw the blame for this on the treatment. Mr. Hume resists my suggestion that fifteen—it may be that this figure should be eighteen—of his cases were too ill to receive a sufficient quantity of lead; but I reject absolutely, not only on the result of our work, but on that of others, the imputation that lead, properly administered, hastens the final issue. There is, moreover, no evidence in the report that it did so in any of the cases treated at St. Bartholomew's Hospital. In general it may be laid down that only occasionally can patients so near death from cancer as to live only thirteen weeks be treated: we, ourselves, have attempted to treat cases of this kind, and only very occasionally have we been rewarded. To base on a few cases imperfectly treated and observed for such a short time conclusions so sweeping as those expressed by Mr. Hume is to ignore every standard of scientific judgement.

What is the truth about these "physical wrecks" referred to by Mr. Hume? The following are the most relevant statements I can find in the report itself: "The reactions following the injection of lead colloid varied considerably, but they were for the most part transitory, and no fatality occurred which could be attributed directly to lead poisoning. The majority of patients only experienced a little headache and loss of appetite. . . ." The report then goes on to say that the patients who received a preparation *not made by us in Liverpool* "experienced more severe reactions. Severe vomiting occurred in all; two patients had rigors, and one of these became deeply jaundiced for ten days." Yet Mr. Hume hides the fact that the patients treated with our preparation did not suffer unduly, whereas those treated with another preparation did suffer severe reactions, for he says that "Dr. Blair Bell seems to be of the opinion that the treatment was not conducted on proper lines. I would remind him, however, that the preparation used was kindly supplied . . . direct from Liverpool." It seems clear that he has endeavoured to make your readers believe that all the patients became "physical wrecks" following the use of a preparation supplied from Liverpool, and, by inference, has implied that this is the inevitable consequence of the treatment rather than of incompetence.—I am, etc.,

W. BLAIR BELL.

Liverpool.

X-RAY DIAGNOSIS.

SIR,—Towards the end of last year there was a discussion in the *British Medical Journal* on the radiologist's activities from the surgeon's point of view and of the surgeon's shortcomings from the radiologist's point of view. Perhaps, in the circumstances, a general practitioner's point of view of one of the contestants—the radiologist—might not be inopportune.

As a general practitioner I owe the radiologist a debt of gratitude for his assistance and guidance in many obscure cases, but there are times when I find him very trying and not a bit helpful, the reason being that there appears to be no hard-and-fast rule followed by the radiologist in his reports on cases submitted to him for expert opinion. For instance, when I send a case, privately, for *x*-ray examination, and want to know if the patient has an arthritis of his spine or a neoplasm, I am rather annoyed when the radiologist volunteers the opinion that the patient is suffering from indigestion. Again, if I ask whether there is a calculus in the kidney it is irritating when he writes back and says it might be appendicitis or merely lumbago! One radiologist refuses to let me see the *x*-ray photograph, while another, although he does send me the photograph and his interpretation thereof, discusses the negative with the patient in his consulting room before ever he writes to me. These are concrete examples.

I submit, Sir, that when one calls in the aid of the *x*-ray expert one wants to know what his *x*-ray investigation shows or does not show; any opinion he may express should, and must, have reference to radiological findings only, and not to conclusions he may have reached merely as a medical man. If I want the opinion of a physician I go to one; on surgical points I appeal to the surgeon; and so, in the case of the radiologist, he satisfies me better so long as he tells me what his *x*-ray examination reveals, and refrains from general deductions.

As to seeing the *x*-ray photograph itself, I contend that, being the doctor in charge of the case (I am referring to cases *x*-rayed privately, and not in hospital), I have every right to see the plate, whether I am considered capable of interpreting it rightly or not. It is for me to judge.—I am, etc.,

VINCENT NORMAN, M.D., F.R.C.S.Ed.

Bradford, Jan. 19th.

DENTAL CARIES AND VITAMIN D.

SIR,—I do not think that "the thoughtful family doctor or parent" will be likely to follow what appears to be the advice of Dr. A. E. Barnes and "simply stop oatmeal and give cod-liver oil or some form of irradiated ergosterol and watch results." The thoughtful parent will probably be more inclined to try the simple, rational, and effective method of preventing caries, which, based on reliable data, has been so very successful during the last quarter of a century that it is now not only recognized by the dental profession, but also authorized by the Council of the Society of Medical Officers of Health in its leaflet on the "Prevention of Decay of Teeth." It is not only because this method has been so successful that the thoughtful doctor is likely to choose it in preference to the irradiated ergosterol and no oatmeal regime. He perhaps may know that Australia has been a great wheat-growing country, and oatmeal can hardly be considered as an appreciable part of the dietary of the people. Sunshine is specially abundant, and the irradiation of ergosterol in the skin is amply provided for. Nevertheless, in Adelaide and Sydney the percentage of school children with carious teeth amounts to nearly 95 per cent.—that is to say, a higher percentage than in England.

A similar tale may be told of New Zealand, where, as in Australia, sunshine is abundant and the food good in quality from the point of view of general health and nutrition. Eggs, milk, butter, etc., give ample supplies of vitamin D, but here, too, the incidence of caries in the teeth of children is much the same as in Australia. It has been noted, however, that caries was less prevalent in the schools which were far away from confectioners' or tuck shops.

By way of experimental evidence, "the thoughtful family doctor" may consult the research of May Mellanby, C. Lee Pattison, and J. W. Proud recorded in the *British Medical Journal* for August 30th, 1924 (p. 355). Therein it was shown that one group of children on "ordinary hospital diet" with *two to three drachms of cod-liver oil daily* continued to develop new carious cavities at about the rate of two per annum—that is to say, at much the same rate as they would on any ordinary hospital diet without cod-liver oil. The same research showed also that associated with variations in the amount of sugar and fermentable carbohydrates there went a corresponding variation in the amount of caries. The evidence was so clear on this point that *Science Progress*, commenting thereon, said: "This work verifies with some statistical exactness the well-known hypothesis that caries in teeth is due to carbohydrates."—I am, etc.,

J. SIM WALLACE.

London, W.1, Jan. 19th.

THE "CARDIAC SIGN" IN CARCINOMA.

SIR,—I am afraid I cannot agree with Dr. Stacey Wilson (January 19th, p. 131) in that I have never found the cardiac dullness absent in simple cardiac weakness following influenza.—I am, etc.,

W. GORDON.

Exeter, Jan. 27th.

LIPIODOL.

SIR,—For injection of lipiodol into the bronchial tree, why not use, instead of tracheal puncture, the via naturalis—the glottis, the route that the anaesthetist uses for his ether? I have used no other. The direct laryngoscope, urethral catheter, and 20 c.cm. Record syringe are all the apparatus required; time, one to two minutes. Children supine in a sheet, shoulders held by a nurse, head by an assistant, no anaesthetic; adults, local cocainization, sitting posture. Cases of bronchiectasis should be previously emptied of their sputum by inversion.—I am, etc.,

JAMES ADAM.

Glasgow, Jan. 27th.

HENRY HICKMAN MEMORIAL FUND.

SIR,—The committee has decided not to close this fund at the end of January as provisionally stated. From a contributor in Canada we gather that there may be medical men abroad and in the colonies who wish to send a donation to the fund, and who have not yet had time to reply. The number of contributors has so far been disappointing.

Without anaesthesia, the great achievements of present-day surgery would be impossible. We ask for further support, not only to recognize Hickman officially for the first time, but to claim this pioneer work for an Englishman, and, in so doing, to stimulate original work in anaesthesia. The honorary treasurer is V. Warren Low, F.R.C.S., 76, Harley Street, W.1.—I am, etc.,

CECIL HUGHES, M.B., Honorary Secretary, Hickman Memorial Fund.

London, W.1, Jan. 28th.

Medico-Legal.

A CHRISTIAN SCIENTIST'S DEATH.

In issuing a death certificate Dr. John Frankland West of Oxford took the unusual course of adding "Christian Science" to the causes—that is, dysentery and extreme wasting—which, in his view, had led to the death of Mrs. Hilda Gwendoline Davis, a Christian Scientist for twenty years.

The evidence at the inquest showed that Mrs. Davis entered Coston House, a Christian Science nursing home, and that Mrs. Robinson, the superintendent, had informed the relatives that while Mrs. Davis was at a Christian Science home there could not be a medical examination or report. Mrs. Davis was removed to the home of her daughter, but such was her outlook that she refused medical attention and would not admit that anything was wrong with her, although she was in a condition of extreme emaciation. Her son-in-law, Mr. J. R. Baker, a university demonstrator in zoology, was asked by the coroner if he had any complaint against the superintendent of Coston House, and he replied that he thought that anybody seeing a person in so emaciated a state should have taken steps immediately to secure medical attention. Dr. West said that when he first saw Mrs. Davis, upon her leaving the home, she was very ill and wasting, and he considered her condition had been definitely aggravated by the lack of medical treatment. If he had not inserted in the death certificate the words "Christian Science," but merely adhered to the textbooks, no inquest would have been held.

The jury returned a verdict of death from natural causes.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons spent this week in committee on the later clauses of the Local Government Bill, together with its schedules, and proposed new clauses. Several aspects of public health administration were debated. Next week the House will be in committee on the Scottish Local Government Bill, to which the Government hopes to move amendments for co-ordinating hospital services, provided that agreement is secured in preliminary negotiations with the voluntary hospitals and the local authorities.

On January 29th the Parliamentary Medical Committee received a deputation from the Poor Law Medical Officers' Association, headed by Dr. Bruce. The subject discussed was the pension rights of Poor Law officers as affected by the Local Government Bill. Assurances which had previously been received from Mr. Chamberlain by members of the Medical Committee were related, and in part reassured the deputation. On the previous day Mr. Neville Chamberlain, receiving a deputation arranged by the Health and Housing Committee of Conservative Members, said he hoped before long to make the Act of 1922, which provides for contributory pensions schemes, a compulsory one for all local authorities, so that all service under local authorities would count equally for pension. Where local authorities had adopted the Act of 1922 no difficulty would arise under the new bill, and he would endeavour to safeguard the rights of those Poor Law officers who wished to remain under the Act of 1896.

The Parliamentary Medical Committee has arranged to receive at its meeting next week a deputation from the Medical Practitioners' Union, which will discuss dispensing under the National Health Insurance Act.

Local Government Bill.

The House of Commons went into committee on January 23rd and resumed the consideration of the Local Government Bill at Clause 68, which provides for the discontinuance of grants. Mr. GATES proposed to qualify this provision by adding the words "other than grants for maternity and child welfare services." He explained that his amendment would keep the grants for these services, as at present, on the percentage system, instead of bringing them under the block system. Last year the maternity and child welfare grant cost £1,052,000. The service was young, growing, and very important. Ante-natal work was only beginning to be considered, and maternal mortality had hardly been considered at all under the schemes. In the last five years the cost of the service had increased by 36 per cent. Sir George Newman had pointed out in his latest report that 25 per cent. of children entering elementary schools suffered from physical defects which could have been prevented by better treatment before entering school. Hitherto half the expenditure under the Maternity and Child Welfare Act had been borne by the Ministry, but under the bill the local authority would decide how much of a block grant should be spent in maternity and child welfare work. Mr. Gates did not think that Clause 86 of the bill provided the Minister with a reasonable safeguard to induce a laggard authority to expedite the work of maternity and child welfare or to increase its amount in view of growth of population. The block grant had originally been fixed for a term of five years. The Minister now proposed that the first period should be three years, the second four, and the subsequent period five years. Mr. Gates considered this to be a great improvement, but said that within three years there might be an increase in the necessities of the neighbourhood which would have to come out of the rates, to the disadvantage of the maternity and child welfare services. An objection had been raised that the percentage grant system implied considerable official interference with local authorities. Mr. Gates said that during many years in local government work he had never heard anything but praise of the official interference by the officers of the Ministry of Health in such work as maternity and child welfare. The advice of these officials had been a great help to local administrators, and had stimulated many lagging authorities. Much of the work connected with maternity and child welfare was, and would be, done by voluntary associations. These were much discouraged by the provisions of the bill. He hoped the Minister would make the voluntary associations feel that they would have full opportunities for work in the future. Some, but not all, had received grants from their county councils. In every case they had received from the Ministry 50 per cent. of their approved expenditure. Under the bill that passed. Whatever the voluntary associations received they would now have to get through the local authorities, and Mr. Gates presumed the figure would be calculated on 1928–29. The Minister had not enough power to see that these associations were recognized by the local authorities. In Mr. Gates's borough of Kensington maternity and child welfare work was started over twenty-three years ago under a medical officer, who got together enthusiastic voluntary workers, and good work was done. Infant mortality in the borough had fallen from 140 deaths per 1,000 to 70. Mr. Gates added that the National Council of Women and other societies supported his amendment.

Mr. GREENWOOD said that the Labour party supported the amendment. Every social service to-day was developing, that being particularly true of maternity and child welfare, the treatment of tuberculosis, and of mental deficiency and venereal diseases. Not a single health service had been utilized to the extent Parliament permitted. In England and Wales last April 847 ante-natal clinics were struggling to cope with the work. Nobody could say they were sufficient. The real opposition to the development of these health services came from the Treasury, which argued that the percentage grant system involved increasing expenditure, which was uncontrollable, and could not be forecast. He contended that the expenditure could be forecast within narrow limits. The State could rule out expenditure which it did not think should receive assistance from the Exchequer. He did not pretend that the percentage grant was in itself an ideal system, but it would get as near the ideal as possible if modified by density of population, poverty, or other necessary factors. Under the Government's scheme every new development of maternity and child welfare work after the grant had been fixed would be a new burden, without a penny from the Ministry of Health. Sir George Newman, in his last report, had said that adequate ante-natal provision, whether provided by doctors or midwives, with the assistance of the municipal clinic or the maternity hospital, was the only sound foundation upon which an effective scheme for a maternity service could be built. Yet Mr. Chamberlain was making that foundation unsound.

Mr. PERCY HARRIS said that in 1916 there were 650 maternity and child welfare centres; in 1928 there were 2,684. He denied they were chiefly found in the richer areas. In London there was more activity in the poorer areas, and in Bethnal Green, the poorest borough in London, there was probably more activity than in any other part of the country.

Dr. VERNON DAVIES said both sides were anxious that nothing should be done to interfere with the development of this service. They simply differed on the best means of dealing with it. He did not agree with Mr. Gates's amendment, being definitely opposed to the percentage grant and in favour of the block grant. Under the percentage grant money was given simply according to ability to pay. The percentage grant encouraged extravagance, and necessitated very careful Government control. These grants were given in the first place as a stimulus. The essential nature of a stimulant was that it was temporary; if made permanent it tended to become a narcotic. All local authorities had the opportunity for some time of taking advantage of the percentage system for maternity and child welfare, but a large number had not done so, from lack of interest, from fear of increase in the rates, or from poverty. The last was the main cause, and on behalf of the poorer authorities the House should welcome the action of the Minister in bringing in the block grant. The Minister had told them that the average grant per head for maternity and child welfare was in the region of 5d., but that in certain towns the block grant would bring the money up to 200l. and even more. No one could say the services would be starved. The money would be there if the public cared to have it. By Clause 86 the Minister could either initiate these services or see they were carried on efficiently. Public opinion, knowing of the new money which would come into the district by means of the block grant, would begin to insist on local authorities using it for this specific purpose. As a keen supporter of maternity and child welfare work, who had initiated and carried on such a service, he was convinced that the day of the percentage grant for maternity and child welfare services was over. Money was essential for the success of a child welfare centre, but what was needed was an enlightened public authority, and above all a conscientious, well-trained, tactful woman as nurse. If they had a thoroughly trained nurse with an instinctive love for mothers and children, and a medical officer with the same characteristics they would have a successful maternity and child welfare service. People would only attend if they had the fullest confidence in the nurse and doctor, and were received with tact, good will, and sympathy. Personnel was much more important than money. The results of the block grant would be an increased number of centres, particularly in necessitous areas, and an efficient standard in all centres. There would be no Government control of expenditure, and that would stimulate initiative and efficiency. The services would benefit by deliverance from the insidious charm of the stimulating cocktail of percentage grants.

Miss LAWRENCE remarked that Dr. Vernon Davies had said that tact and sympathy were a good substitute for money. She denied that Clause 86 gave the Minister power to insist on maternity work being undertaken. No clause asking for a reasonable standard could turn optional services into compulsory ones. These services, with tuberculosis, venereal disease, and other services, were optional. She quoted evidence given on behalf of the Ministry of Health to the Royal Commission on Local Government to the effect that the Minister had no power to compel local authorities to institute maternity and child welfare clinics

but that the lever of a substantial grant had in practice achieved a fair efficiency. At present the Minister could make proportional grants direct to voluntary societies. Under the bill all they would get was whatever the local authorities gave them by way of a scheme approved by the Ministry. The Labour party stood for a logical extension to mental deficiency, tuberculosis, venereal disease, and care of the blind of the principles which it had advocated on this amendment. Local authorities had to be bribed by a 75 per cent. grant to take up venereal disease work. Would they carry it on when every penny they spent had to be taken out of block grants handed over for other purposes?

Sir DOUGLAS NEWTON said the new system would be better for voluntary organizations interested in maternity homes, which at present had to apply to many boards of guardians for contributions. In future they would apply to major authorities, which were more likely to be sympathetic.

Lady ASTOR said that under Clause 83 the voluntary associations were in a stronger position than ever before. Health services had not grown because of popular demand but in spite of general apathy, because they were inspired by the central authority, working mainly through voluntary associations. Local authorities seldom moved unless they were prodded by the Minister of Health. The problem of the children between 1 and 4 years of age had to be faced. Of 82,000 children under 14 who died during 1928, 25,000 were between 1 and 4 years of age.

Mr. CHAMBERLAIN said the Registrar-General's figures for 1928 showed that the infant mortality rate came down last year to 65 per 1,000, being 4 per 1,000 lower than the previous best record in this country. The maternity and child welfare service had materially contributed to that tremendous improvement. The Treasury was unlikely to impose a change of policy regarding a service in which the Minister of Health took the keenest interest and where it could only gain a few hundred thousand pounds. It had been said that the maternity and child welfare service was not popular. The mental deficiency service was far more unpopular, and therefore if they exempted the former service from the block grant on that score it was difficult to see where they could draw the line. At the Ministry of Health he considered the reports which came in from all localities, and he did not find the present maternity and child welfare system satisfactory. He agreed with Mr. Greenwood that there should be many more ante-natal clinics. To show how the present system worked he cited the grants per child under 5 years which were paid to four poor towns—Gateshead 27d., Dudley 21d., Tynemouth 36d., and Merthyr Tydfil 43d. Manchester received per child 128d., Liverpool 107d., Leeds 140d., and Eastbourne 209d. How could they say that kind of distribution was likely to encourage adequate maternity and child welfare services in poorer districts? As the service was to-day the average cost over the country was 5d. a head. Under the Government scheme many towns and counties were going to gain many times that amount. He had offered a guarantee of a shilling a head, but that was only to the few places which would not gain more under the scheme. It was true that under Clause 86 he could not force local authorities to give adequate maternity and child welfare services, but he would have a powerful lever in being able to take away from the grant which they had already got. Instead of actually using that lever he would only have to whisper into the ear of the local authority "Clause 26." No local authority would resist a reasonable demand for adequate services of this character or risk the loss of the grant. He attached importance to the work done by voluntary associations, and under Clause 83 the Minister himself would see that their interests were looked after. In the case of London the bill provided that the Minister should make a scheme providing how much the London County Council and how much the borough councils were to contribute to any particular voluntary association. In the country the inspections of voluntary work by the officers of the Ministry would go on in a different form, and the Minister's approval had to be obtained to the scheme under which the contributions of the local authorities to the associations were fixed. He was putting a clause down on the paper to give him power, after consultation with the local authority, to revise a scheme during a quinquennium when an association desired to extend its services, or when some body of people desired to form a new association. Again, if Parliament should impose on local authorities a new service which would mean new expenditure by them, then it would be just that Parliament should make an additional contribution towards the cost, and he had put down a new clause declaring this to be the intention of Parliament. Finally, he remarked that the whole system introduced by the bill would have to be reviewed before many years.

Mr. PALIN said that as an economy the money spent on infant and maternity welfare centres was the wisest expenditure a municipality could make.

Mr. JAMES HUDSON represented that Dr. Vernon Davies had said that sympathetic and tactful nurses and voluntary workers could do all that was required. He contended that skilled medical attention was required. Huddersfield had recently been divided into three parts, and in one area, instead of leaving the care of mothers and children to sympathetic persons and nurses, an arrangement was made for a monthly visit before and after birth by a skilled medical man. Medical assistants were specially appointed for the job. In the third of the town where this experiment was tried the death rate was reduced by 10 or 11 per 1,000 during the brief period of the experiment. He regretted that Huddersfield Town Council had not applied the system in the other areas of the town.

Mr. CECIL WILSON said that in Sheffield infant mortality had dropped about 15 per cent. since 1923, but mortality from puerperal fever and other accidents of childbirth had gone up 83 per cent. The number of cases going to the maternity centre had increased by 238 per cent. since 1921.

Dr. FREMANTLE said that, as an old medical officer of health, he had been in close touch with the voluntary associations and in co-operation with them for thirty years. When the bill was first announced he had shared the anxiety at the abolition of the percentage grant, but now he was convinced that the bill, under certain conditions, was a great advance, and they had to make the best of it. Medical officers of health must recognize that the new principle of weighted population which had been introduced for calculating the block grant was an interesting new factor in public health administration. The weighting of the population according to the number of children under 5 years old and the number of the unemployed had got possibilities. A great deal depended on how the local authorities were going to use the powers given them under this bill. Those who had the administration of these services felt again and again that it was impossible to move because of the lethargy of many local authorities. Some, especially in industrial centres, were keen, some indifferent, and some actually hostile. Under the bill there would be opportunity for getting greater interest and for focusing attention upon local government. If they could get a largely increased interest in local government they could trust the local authorities to carry out the block grant system properly, with great advantage compared with the present system.

Mr. LANSBURY said that under the percentage grant system the death rate among children in the poorer districts of London, Leeds, Bradford, and Bristol had been more than halved. The least falling off of money would mean an increase in the death rate among children.

Mr. GATES, in view of the sympathetic speech by Mr. Chamberlain, asked leave to withdraw his amendment. Leave to withdraw was refused, and on a division the amendment was defeated by 130 to 206, a few Conservatives voting for it. Clause 68 and subsequent clauses were then added to the bill, and further progress was made with the bill on the following day, January 24th.

On January 25th the House again went into committee on the bill and discussed Clause 75, authorizing the Minister to prepare with county and district councils schemes as to maternity and child welfare.

Miss SUSAN LAWRENCE asked where the money would come from. The clause, she said, proposed to give the Minister power, wherever in a county any authority had shown willingness in the matter, to force the county to spend as much as might be necessary out of the county apportionment on this service. The organization of this service, if properly carried out, would cost a great deal. Institutional treatment for this class of service was backward. They had only 2,460 local authority beds at maternity hospitals. Only 122 local authorities had institutional treatment for puerperal fever, and only 252 had arranged for special nursing. There were only 93 day nurseries in England and Wales. They ought to spend £1,000,000 extra to deal with this question, and there should be more severe compulsion than was proposed in the bill. The reform proposed in the clause was good in itself, but would in the long run be carried out at the expense of the ratepayers.

Dr. FREMANTLE said he would consider the proposal made by the clause in the light of the practical experience he had as a county medical officer of health. In gingering up local authorities in his area to undertake increased expenditure he had been no exception among medical officers of health. The difficulty hitherto had been that under the Local Government Act, 1888, the power of county councils over district councils had been shadowy. All that could be done was to try to persuade them. As a rule insufficient money was available, and that was why these services had not been developed in the past. In the future more money would be available for every county and county borough, and there was a great possibility of its being expended. The county medical officer of health would be able to go round to the district medical officers of health, and if told that an authority had decided not to introduce these services, he could urge that the question be raised again. Altogether there would be a good case for starting new centres and developing the work. Mr. Palin had assumed that local authorities had not been stirred up in Yorkshire, but Dr. Fremantle said he knew a medical officer in the West Riding who was very active in that way. Dr. Fremantle thought the clause would be a great help to maternity and child welfare.

Dr. VERNON DAVIES said that as he understood the clause the centres established by district councils would be worked independently of the county council, which would have no direct control

over their administration or *medical* service. Such centres were intended to work in a consultative capacity and only to a small extent as treatment centres. The maternity and child welfare centres could not undertake the treatment of cases of tuberculosis, *venereal disease*, or early mental trouble, neither could they treat the serious diseases of women. They would have to distribute the serious cases to the hospitals, and the expense would not amount to very much. The fear that this service would be hampered by the bill was groundless.

Miss WILKINSON said all the House *recognized the amount* of good work done by Dr. Fremantle on such questions, but she suggested that he was wrong in his *interpretation* of Clause 75. It did not say what would happen to the districts which had not a maternity and child welfare committee. Maternity homes in crowded areas, toward the provision of which the Ministry had promised 50 per cent. of the maintenance charges, were being held up pending the passage of this bill.

Mr. RENNIE SMITH said that the nation as a whole lagged behind in pre-natal effort and in the co-ordination of the best scientific treatment round about the actual birth. A considerable allocation of money was needed to get trained medical officers and nurses in the areas where they had not enough, and in many other areas where these services did not exist.

Mr. ARTHUR GREENWOOD said that in many county areas where there were only a few maternity and child welfare schemes in operation the general sense of other local authorities in the counties would be against the expenditure of additional money, and the Minister would be unwilling to apply *much* pressure.

Mr. CHAMBERLAIN said he had listened in weariness of spirit to fallacies and *misstatements*. If these health *services were made* compulsory the Government must lay down precisely what each local *authority had to do*. Maternity and child welfare services in a county were normally the work of the county council, but certain county districts had been given powers under Acts of Parliament to carry on these services in their own areas. They were islands in the county. In the new county apportionment the Government included the grants which had hitherto been given to these separate areas, and the purpose of the clause was to determine the amount of money which was to be taken out of the county *apportionment* and to be handed to the authority which had to carry on this service in its own area. There were only about 250 of these authorities, and there was no case where one of them was doing nothing. He begged the House not to take too gloomy a view of the progress of the maternity and child welfare service. He was doing all he could to improve it, and hoped to have an opportunity of doing more soon. The amount in the Labour party's estimates for maternity and child welfare service was £814,000. This year it was £1,052,000. In 1924–25 there were 639 ante-natal clinics in the country. Now there were 847. The number of beds in maternity homes and hospitals recognized by the department had risen from 2,001 in 1924 to 2,478. They were making substantial progress, and under the Government scheme there would be ample funds for all local authorities which had the power to provide maternity and child welfare services as fast as they would find possible.

Clause 75 was added to the bill by 158 to 78. Discussion followed on clauses *dealing with Exchequer grants*.

The House on January 28th again considered the bill in committee. On Clause 83, which deals with *contributions* by councils to voluntary associations in respect of maternity and child welfare, Sir LESLIE SCOTT *moved an amendment to impose a* statutory obligation on county and county borough councils to consult voluntary associations doing maternity and child welfare work before framing their schemes.

Mr. NEVILLE CHAMBERLAIN said that the amendment was unnecessary, because it was impossible for any council to frame a scheme of that kind without consulting the voluntary *association*. The clause provided that the county councils or county borough councils were to prepare schemes for securing payments by them of annual contributions towards the expenses of voluntary associations. To know what these expenses were the councils must *know* what the associations were doing, were able to do, and proposed to do in future. The Minister of Health also had to approve of the schemes, and if the schemes were submitted without consultation with the voluntary associations it would be open to the associations to represent to the Minister that they had not been consulted. The amendment was withdrawn.

Mr. HURST moved an amendment giving power to the Minister of Health to include in the schemes prepared by county councils provisions whereby contributions towards the *costs* of inmates in a maternity home within its area might be enforced against the council of any other county or borough where an inmate normally resided before entering the home. He said that the amendment would enable the unmarried mother to avoid local scandal by going into a home at a distance.

Mr. CHAMBERLAIN said it would be a mistake to *make it more* difficult for maternity homes to take in unmarried mothers from other localities. In the past direct grants had been given from the Exchequer to the homes, but in future the grant would be given to the local authority in whose district the home was situated. The local authority would not have discretion to spend the *money on* anything else. For seven years it would receive 75 per cent. of the grant previously given, for the next five years the grant would be 50 per cent., and for another five years 25 per cent. The amendment was rejected.

Sir KINGSLEY WOOD moved an amendment giving power to the Minister of Health, after consultation with the local authority concerned, where it was desired to start or further a maternity or child welfare scheme, to alter the scheme so as to provide for such contributions, or increased contributions, as he considered just. He said that with this amendment and the original clause in the bill the Government was giving a very strong position to the voluntary associations carrying out this work.

Dr. FREMANTLE said that his name and that of Major Hills were down to an amendment earlier on this clause, but he purposely did not move it because this amendment covered the same ground. He had tabled his amendment because the clause did not provide for the future expansion of this service. It was put *down on* behalf of the Midwives' Institute and the Queen Victoria Jubilee Institute for Nurses. Those professional bodies, which were largely neglected by public opinion, were at the bottom of the working of these maternity associations, and they would, he believed, be abundantly satisfied by this amendment, which seemed to him to cover the substance of the amendment which he had *put down* and also other points which he had in mind. He hoped that there would be a possibility of covering now, for the first time, the whole of the counties with the work of the county nursing *associations in nursing* and midwifery work, *which had been* extending, but extending slowly. He hoped, speaking on behalf of the midwives, that the clause as amended would be successful.

The amendment was agreed to, and Clause 83 was added to the bill.

On Clause 84, which provides for contributions by councils to voluntary associations in respect of *other health services*, Sir LESLIE SCOTT moved an amendment providing that the Minister should, before the beginning of *each fixed grant period*, make a *scheme* providing for the payment of contributions by councils of counties and county boroughs of such amounts as *might be specified* in the scheme, to voluntary associations which undertook to provide, centrally or locally, services for the *welfare* of defectives, including the ascertainment, assistance, or supervision of defectives whilst not in institutions. As the clause now stood some of them feared it might limit the services for which the grants under the clause might be given. A great deal of the best work for mental defectives was not done by the local authorities, and he wished to make sure that there would be no limitation in future *in grants* for work done as assistance to the local authorities.

Sir T. INSKIP (Attorney-General) said he could give Sir Leslie Scott the assurance he desired, and the amendment was accordingly withdrawn.

Sir WALTER GREAVES-LORD moved an amendment providing that the Minister of Health should, before the beginning of each fixed grant period, make a scheme providing for the payment to county and county borough councils of such amount as might be specified in the scheme to the central council of an approved organization which provided services, in the nature of general publicity and educational propaganda, in furtherance of the prevention and treatment of venereal disease. He could not understand why the Government had thought it necessary in the bill to take a course which would destroy to a large extent the activities of one voluntary association—the British Social Hygiene Council—whose work had been recognized not only by the Government, but by the Royal Commission on Venereal Disease, and had been due to the expressed satisfaction of the Ministry of Health. In health services, such as maternity and child welfare, and the care of mental defectives and of the blind, would be affected if anything was done to diminish the efficiency of the measures taken for the prevention and curative treatment of venereal disease. The amendment would enable the Minister to make an equitable scheme, which would provide for a contribution based upon £ per 1,000 of the population. If, however, the Minister could deal with the matter as he desired in Clause 86 of the bill he would be content.

Sir KINGSLEY WOOD resisted the amendment. He said that Sir Walter Greaves-Lord, following, he supposed, the precedent already established in relation to the maternity and child welfare services, sought to secure that local authorities should be obliged to pay an annual contribution to the British Social Hygiene Council or some corresponding body. The Minister of Health shared with the mover of the amendment his appreciation of the work which that council had achieved, especially in the earlier days, when that kind of work was much more unpopular than at present. Many local authorities were actively engaged in the work of stamping out the disease. During the present year some £7,500 had been spent by them. Many local authorities desired to include venereal disease as one of the subjects in their general scheme of [illegible] propaganda. There was a distinction between the position of voluntary agencies which were carrying out maternity and child welfare work and those undertaking purely propaganda work. The responsibility for the health services rested with [illegible]

authorities, who would strongly resent being obliged to contribute towards the expenses of a service which they might not care to apply. He saw no reason why the work of the British Social Hygiene Council should not continue in conjunction with the work of local authorities, but there was considerable objection to giving this compulsory power to the Minister of Health and compelling them to contribute. That was going to an extreme length. The Government was proposing, in a new clause standing in the name of Mr. Chamberlain, to give power to the Minister to pay a contribution to voluntary associations out of the sums payable out of the general Exchequer grant.

Dr. FREMANTLE supported the amendment. He said that he took up this attitude with the greatest reluctance and after the most sincere and continuous study of the bill. As a matter of conscience, he felt that he was bound to do so. The situation had not been met by the Parliamentary Secretary, nor by anything which he had heard from those connected with the Ministry of Health. There was a strong feeling on this subject.

Mr. CHAMBERLAIN said he admitted at once that the amendment had received very weighty support, and he opposed it with very considerable reluctance, partly because he valued very much the work done by the British Social Hygiene Council, work in which in the past he had taken considerable interest himself, and partly because he admired the devotion with which Sir W. Greaves-Lord had thrown himself into a business which certainly was not of a particularly popular character. The Minister of Health was in quite a new position in regard to all these services. It was only right that the local authorities should perform their duties in an adequate manner, and if they were not doing so because they would not use the services of this particular body, then it was quite clear that he would have a very strong case for asking that they should make their contribution. He asked members to think well before they compelled these responsible bodies to contribute to something of which they might not approve. He, as the responsible Minister, did not desire to see this body disappear, and he should take all the steps he could within the limits of the bill to assist it.

Dr. DRUMMOND SHIELS said that the distinction which the Minister had drawn between making a claim on the local authorities to support the central body and his refusal to compel them did not seem to go very well together. The right hon. gentleman admitted that the national propaganda was essential for the prevention of these diseases, and at the same time he refused to give support to the body which dealt with them.

[At this point the guillotine fell on the debate, and the amendment was defeated by 204 votes to 95. The clause was then agreed to and the debate adjourned.]

*** The conclusion of the debate on the Local Government Bill is unavoidably held over till our next issue.

Radium Requirements and Supplies.—Mr. CHAMBERLAIN stated, on January 24th, that the subject of radium requirements and supplies was still under consideration by a subcommittee of the Committee of Civil Research. On January 28th Sir KINGSLEY WOOD told Mr. R. Morrison that the subcommittee of the Committee of Civil Research would not report to the Ministry of Health on the supply of radium. The Minister of Health had arranged for the inquiries made on the subject in the House of Commons to be brought to the notice of the subcommittee, and he trusted that their report would be available at an early date.

Post-vaccinal Encephalitis.—In the House of Commons, on January 25th, Mr. GROVES called attention to the fact that an inquest into the death of a boy at Castleford in November, 1928, from post-vaccinal encephalitis had returned a verdict of death from natural causes, whereas the verdict on a boy who died in Poplar Hospital from the same cause on January 14th had been death from misadventure. Mr. CHAMBERLAIN said that both deaths had been classified under the heading "vaccinia" for the Registrar-General's mortality statistics.

Special Institutions for Ex-Service Medical Cases.—On January 23rd Colonel STANLEY, answering Mr. Smedley Crooke, said that the two special institutions which the Ministry of Pensions set up in 1923 with the assistance of the Board of Control, and in conjunction with the general medical hospitals, were specifically designed for ex-service medical cases in which the Ministry is advised that a chance of recovery or improvement is offered by occupational training and instruction. Incidentally Colonel Stanley deprecated as inaccurate and needlessly offensive the description of mental hospitals provided under the Lunacy Acts as "pauper lunatic asylums."

Treatment of Enlarged Tonsils.—Mr. ROBERT RICHARDSON asked Lord Eustace Percy, on January 24th, whether, in view of conflicting medical testimony on the advantage of, or necessity for, the extraction of enlarged tonsils, he would recommend local educational authorities to bring to the notice of their medical officers the fact that there was an alternative treatment, and advise them not to prosecute parents who desired to follow such treatment rather than to have recourse to the operation. Lord EUSTACE PERCY did not think the course suggested was necessary. Medical officers of education authorities knew there were alternative methods of treatment for enlarged tonsils. Operative treatment would only be recommended by them when other methods had been tried and failed. In the reports of the Board of Education for 1921 and 1923 the position of the Board was indicated, and it was clearly stated that the Board of Education had consistently advised that operation should not be undertaken except with the full consent of the [illegible] the child. In reply to a similar question [illegible] centres, it was stated that it was not [illegible] centres to advise the removal of tonsils, but to refer children needing treatment to a hospital or private doctor for advice on the appropriate form of treatment.

Idiosyncrasy to Chemical Poisons.—Mr. DUFF COOPER (Financial Secretary to the War Office) told Mr. Will Thorne, on January 24th, that his attention had been drawn to a report of the inquest on a research worker at Woolwich Arsenal, where the coroner recorded a verdict that death was accelerated by the deceased having come in contact with some chemical poison allied to nitroglycerin. Mr. Cooper said he was advised that nitroglycerin poisoning was extremely rare, and might imply a predisposition in the individual which could not be ascertained beforehand. Instructions were being issued that if any worker felt indisposed as a possible result of contact with the material he was using he must at once report the fact to his superior.

Notes in Brief.

A bill to regulate the sale of reconstituted cream, presented in the House of Commons on January 24th, is backed by Dr. Vernon Davies.

Mr. Chamberlain states that available statistics do not allow properly comparable figures to be given for the death rates in the United States, Germany, and France from small-pox and from pulmonary tuberculosis.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on January 24th the following medical degrees were conferred:

D.M.—C. J. Fuller.
B.M.—S. B. Davis.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on January 26th the following medical degrees were conferred:

M.D.—A. D. Porter.
M.B., B.CHIR.—W. J. Lloyd.
B.CHIR.—S. D. Isaacs, W. E. Underwood.

UNIVERSITY OF LONDON.

THE Senate has accepted with thanks an offer of the committee of the Bayliss-Starling Memorial Fund of the sum of £2 500 for the establishment at University College of a scholarship for training in physiology and biochemistry to commemorate the connexion with physiology of Professors Sir William Maddock Bayliss and E. H. Starling.

It has been resolved to institute an academic diploma in clinical pathology.

The degree of D.Sc. in Anatomy has been conferred upon Mr. H. A. Harris, an internal student of University College, for a thesis in the form of a series of memoirs dealing with the problems of bone growth, radiology, and teratology, published in various medical and scientific journals.

The degree of D.Sc. in Psychology has been conferred upon Mr. J. C. Flugel, an internal student of University College, for a thesis entitled "Studies in mental oscillation and related functions."

Mr. H. L. Eason, C.B., C.M.G., has been reappointed a member of the General Medical Council.

Professor W. W. Jameson has been appointed to represent the University at the fortieth congress and exhibition of the Royal Sanitary Institute, to be held at Sheffield in July.

The William Julius Mickle Fellowship for 1929, of the value of about £250, has been awarded to Dr. A. Sterling Parkes, in respect of the work he has carried out during the past five years on the physiology and biochemistry of the organs of reproduction.

UNIVERSITY OF MANCHESTER.

DR. J. F. WILKINSON has been appointed director of the laboratory of clinical investigations, in succession to Dr. W. Morrell Roberts. Dr. Jethro Gough has been appointed demonstrator in pathology.

LONDON INTERCOLLEGIATE SCHOLARSHIPS BOARD.

Medical Scholarships.

THE London Intercollegiate Scholarships Board announces that an examination for nine medical scholarships and exhibitions, of an aggregate total value of £1,170, will commence on April 16th. They are tenable at University College and University College Hospital Medical School, King's College and King's College Hospital Medical School, and the London (Royal Free Hospital) School of Medicine for Women. Full particulars and entry-form may be obtained from the Secretary of the Board, Mr. S. C. Ranner, M.A., the Medical School, King's College Hospital, Denmark Hill, S.E.5.

Obituary.

ANDREW LITTLE, M.B., C.M.,

Consulting Surgeon, Royal Eye and Ear Hospital, Bradford.

THE medical profession in the Bradford district learned with deep regret of the death, on January 9th, of Dr. Andrew Little, in his sixty-fifth year; he had been an outstanding figure in their midst for more than thirty years.

Andrew Little received his medical education at Aberdeen and the London Hospital, graduating M.B., C.M.Aberd. in 1889. After holding appointments in London and Liverpool, he settled first in the Burnley district, and later removed to Bradford. Early in his medical career he devoted himself to eye, ear, throat, and nose work, a combination of specialties which was common in the North of England at the time. He became associated with the Royal Eye and Ear Hospital in Bradford as far back as 1892, and was one of the full surgeons there from 1901 to 1918; from 1911 to 1922 he was honorary laryngologist to the Bradford Royal Infirmary. At the end of the war he gave up his active hospital duties, continuing at the Royal Eye and Ear Hospital as honorary consulting surgeon.

Dr. Little was widely recognized as a leading authority in throat, nose, and ear work in the West Riding; he had built up a large consulting practice, from which he retired in 1922 to live in Westmorland. His activities and interests were many and varied, and he was at one time co-editor of the *Caledonian Medical Journal*, but perhaps he was most of all attached to the preventive side of his own particular work. He was invited by the Bradford City Council in 1913 to act as their consulting ophthalmic and aural surgeon, a position which he held for six years; during this time he greatly developed the municipal work along lines satisfactory alike to the council, the public, and the medical profession. His appointment was one of the first of its kind in the country, and by his keenness, shrewdness, and ability to inspire others he laid the foundation of that happier state of co-operation which exists in all branches of the medical profession—hospital, private, and municipal—in Bradford to-day. He threw himself whole-heartedly into the aspects of his work which affected child life, and he recast the principles of the treatment and education of the child with defective vision, the outcome of which was the new Bradford Myope School.

To all who knew him, Andrew Little was a valued friend and a helpful colleague; his passing leaves a sense of deep personal loss. His illness was borne with fortitude and resignation, and his end came as the completion of a life's duty faithfully and fully done. His wife predeceased him by one year. He leaves behind him an adult son and daughter, at whose house he died. J. B.

His many friends in Scotland and England will share our regret in recording the death from pneumonia following influenza of Dr. GEORGE SMITH SOWDEN, which took place at Elgin on January 19th. Dr. Sowden was born of Scottish parentage in Madras forty-six years ago, where he spent his early boyhood, and then came to this country to be educated at Elgin Academy and Edinburgh University, graduating in arts and medicine in 1909. After graduation he spent some years at Newcastle-upon-Tyne and Kirkby Stephen. On the outbreak of war he volunteered for service and served as surgeon-lieutenant on board H.M.S. *Colossus*. After the war he took his degree of M.D. at Edinburgh, with commendation, and settled in practice in Elgin in succession to the late Dr. Dickson. He was a man of many and varied interests and public spirit: a keen antiquarian, he was recently elected a Fellow of the Society of Antiquarians; an authority and frequent lecturer on Jacobite history; an enthusiastic Freemason and Rotarian; a good golfer and president of the Moray Golf Club. To the British Medical Association he gave almost continuous service throughout his professional life, first as member of the executive, vice-chairman and chairman of the Kendal Division, and latterly as secretary of the Banff, Moray, and Nairn Division and member of the Scottish Committee and of the Insurance Acts' Subcommittee. All his work was marked with zeal, thoroughness, and patience. A cultured and courteous man, a loyal friend, and untiring worker for the common good, his loss at so early an age is much to be deplored. He is survived by a widow and one daughter.

Dr. JAMES MUNCE, who died on January 20th after a brief illness, had been in practice at Lisburn, in county Antrim, for many years, and was held in high esteem by his colleagues in that district. He received his medical education at Queen's College, Belfast, and in 1896 obtained the diplomas L.R.C.P., L.R.C.S.Ed., and L.R.F.P.S.Glas. Soon after qualifying he left Saintfield, county Down, for Lisburn, on his appointment as dispensary medical officer for the Drumbeg district. In Lisburn he became associated with the Antrim County Infirmary, and acted as anaesthetist for twenty-five years. Dr. J. W. Peatt sends the following appreciation: It is with a deep sense of loss that those who knew him have heard of the death of Dr. James Muncе. In Lisburn he was looked upon by all classes as a trusty friend, an able practitioner, and a Christian gentleman. His quiet confidence gave assurance and comfort to all, and in moments of sorrow and trouble many instinctively turned to him. Of an unselfish character, he gave his services freely to the poor, without thought of recompense. His passing has caused great regret, equally among his colleagues and the members of the general public.

Dr. JOHN FOLLETT BULLAR, who died from drowning on January 24th, aged 74 years, was born at Bassett, near Southampton, and was educated at the University of Cambridge and at St. Bartholomew's Hospital Medical School. He graduated B.A.Camb. in 1877, and M.A. and M.B. in 1883; in the following year he obtained the diploma of F.R.C.S.Eng. After serving as ophthalmic house-surgeon and assistant demonstrator of anatomy at St. Bartholomew's Hospital he went to practise at Southampton. There he founded the Southampton Free Eye Hospital, to which he became surgeon and afterwards consulting surgeon, and he was also consulting surgeon to the Royal Hants County Hospital, Winchester. He removed to Guernsey some years ago and became very popular on the island. During the war Dr. Bullar served as an ophthalmic specialist with the rank of captain R.A.M.C. He and Mrs. Bullar were returning to Guernsey from a holiday in the South of France, and use was being made of a seaplane to make the journey from Corsica to the mainland when the machine turned turtle in the harbour at Antibes, and both were drowned.

The following well-known foreign medical men have recently died: Dr. EDMUND LASKOWSKY, formerly professor of anatomy at Warsaw, and inventor of a fluid for the preservation of anatomical specimens, aged 87; Professor PAUL KUBINYI, director of the first gynaecological clinic at Budapest, aged 58; and Dr. PIETRO DE AMICIS, an eminent paediatrist of Genoa.

The Services.

HONORARY SURGEON TO THE KING.

SURGEON VICE-ADMIRAL ARTHUR GASKELL, C.B., O.B.E., Medical Director-General of the Navy, has been appointed an Honorary Surgeon to the King.

DEATHS IN THE SERVICES.

Lieut.-Colonel Stafford Mary Adye-Curran, R.A.M.C.(ret.), died at Omagh on December 28th, aged 48. He was born on July 11th, 1880, was educated at the Catholic University, Dublin, and took the L.A.H. in 1900, also subsequently, in 1907, the D.P.H. of the Royal College of Surgeons in Ireland. After qualifying, he went out to South Africa as a civil surgeon, and, after nearly a year's service in that capacity, joined the R.A.M.C. as lieutenant on July 26th, 1901. He attained the rank of lieutenant-colonel on December 26th, 1923, and retired on March 24th, 1925, when he joined the Reserve of Officers. He served in the South African war, taking part in operations in the Transvaal, and received the Queen's medal with five clasps.

Medical News.

THE German Balneological Society (Balneologische Gesellschaft), at its jubilee congress held in Berlin last week, elected Dr. R. Fortescue Fox an honorary member. This honour was conferred in recognition of Dr. Fox's work as chairman of the International Society of Medical Hydrology, and as a personal tribute and expression of the esteem in which he is held by medical hydrologists in Germany.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Monday, February 4th, at 5 p.m., Sir Henry Simson will give a lecture on "Some obstetric pitfalls," at the Medical Society, 11, Chandos Street, Cavendish Square, W.1, and on the same day, at 2 p.m., Mr. Mortimer Woolf will give a demonstration in general surgery at the Queen Mary's Hospital, Stratford. A demonstration on "Rheumatism and the cardiac child" will be given at the Royal Waterloo Hospital, at 2 p.m., on Tuesday, February 5th, by Dr. Gerald Slot. On Wednesday, February 6th, Mr. Mortimer Woolf will give a demonstration on "Tumours of the thyroid gland and their treatment," at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C.1, at 4 p.m. Special courses will be given, from February 11th to 22nd, at the Chelsea Hospital, in gynaecology; from February 11th to March 9th, at the St. John's Hospital, in dermatology (pathology demonstrations will also be arranged); from February 25th to March 9th, at the Hospital for Sick Children, in diseases of children; and from February 25th to March 2nd, at the Brompton Hospital, in diseases of the chest. Copies of all syllabuses and information regarding the general course of the Fellowship may be obtained from the secretary, 1, Wimpole Street, W.1.

THE Royal Sanitary Institute has arranged a course of training for army officers and professional men in meat and food inspection and canteen supplies commencing on Monday, February 18th, and another beginning on Friday, February 22nd, for meat and food inspectors. Syllabuses of the lectures and examinations are obtainable from the secretary of the Institute, 90, Buckingham Palace Road, London, S.W.1.

THE Swiney prize for 1929 has been awarded by the adjudicators, the Royal Society of Arts and the Royal College of Physicians, to Dr. Sydney Smith, Regius Professor of Forensic Medicine in the University of Edinburgh, for his work "Forensic Medicine." Dr. Swiney, who died in 1844, left a sum of money to the Royal Society of Arts to provide a prize every fifth year for the best published work on jurisprudence. The prize, which consists of £100 and a silver cup of the same value, was offered this year on the 85th anniversary of the testator's death for a work on medical jurisprudence.

ON the occasion of the recent celebration of the centenary of the foundation of Cairo University and the Congress for Tropical Medicine a tour was made last December by sixty-seven medical practitioners from Germany, Austria, Danzig, Holland, and Poland to Egypt and Palestine, under the direction of Dr. F. Barach of Vienna.

THE Rizzoli Orthopaedic Institute in Bologna announces that a prize of 3,500 lire is offered for research in orthopaedics by medical practitioners in Italy and elsewhere. Further information may be obtained from the president of the Rizzoli Institute.

THE British College of Nurses, which was founded in 1926 with an endowment of £100,000, has issued a circular explaining its objects and indicating the advantages to trained registered nurses of membership. Its purpose is to raise the status of the nursing profession by organizing special courses of instruction and by the institution, in the future, of examinations—of a higher standard than that for State registration—for admission to its membership and fellowship. Meanwhile, it offers the benefit of facilities for education, scholarships, legal defence, pensions, and insurance; and of the use of the reference library and club rooms at its headquarters at 39, Portland Place, London, W.1, whence further information may be obtained.

AT a meeting of the Joint Tuberculosis Council on January 19th Dr. McDougall presented a report on behalf of the Employment Committee; in the discussion which followed Dr. Varrier-Jones emphasized the importance in colony work of attention to the patient's mentality, and of providing opportunities for any who showed exceptional ability to rise to the position of supervisers and teachers. The committee was asked to report
employment schem
residential institutions. Dr. Brand reported that during 1928 14 had attended Sir Henry Gauvain's post-graduate course at Alton, 18 had been present at Dr. Varrier-Jones course, and 30 at the one arranged by Dr. Gloyne at Victoria Park Hospital. During 1929 he proposed to arrange courses in surgical tuberculosis, a course in artificial pneumothorax therapy and the interpretation of radiograms, and a French course at the University of Paris during Easter. After the meeting the council was entertained to lunch at the Hotel Russell by Sir Henry Gauvain.

THE *British Journal of Anaesthesia* announces the award of the £50 prize for the best inhalation research effort made by a citizen of the British Empire in 1928, to Florence Stephen, M.B., Ch.B., M.Sc., of the Manchester Royal Infirmary Research Department. The prize is in memory of the late Dr. S. R. Wilson of Manchester.

THE International Society of Medical Hydrology recently published a report on certain African waters. The information laid before the council proved of so much interest that the officers of the society took advantage of the visit to England of the eminent South African chemist, Professor M. Rindl of Grey University College, Bloemfontein, to hear from him some account of the chemistry of these waters. A small meeting of hydrologists and chemists was accordingly held on January 24th, the High Commissioners for South Africa and New Zealand sending representatives. Professor Rindl stated that he had been drawn to the subject in the search for home supplies of potash, and though his survey of the springs had failed to provide any results in that direction, he had made and published a preliminary survey in the hope of arousing medical and other interest in this important national asset. He found that the analyses of the waters were often incomplete and out of date, that insufficient clinical data were forthcoming, and that bathing facilities were inadequate. Many of the springs had a long history of use, first by the aborigines and then by the farmer-settlers, some still being used only in the most primitive way. Yet the waters themselves were well worthy of study and development. They were principally either sulphurous or chalybeate, no important brine springs being known, in spite of the extent of the surface "salt-pans." Seven of the springs had temperatures exceeding 105° F., the hottest being 158° F. Many were said to be radio-active, and one had a fair proportion of helium.

DR. PERCY COLEMAN, who for 30 years has been connected with the Clacton and District Hospital, has been presented with his portrait in oils by Harold Knight, A.R.A., an album containing the names of the 335 subscribers, and a wallet containing the residue of the fund. The presentation was made at a very largely attended meeting at the Grand Hotel, Clacton, presided over by Brigadier-General K. J. Kincaid-Smith, D.S.O., and attended by the medical practitioners and well-known personalities of the town.

THE following members of the medical profession were called to the Bar on January 28th: Drs. F. W. Kemp and G. Irving (Middle Temple), Dr. P. S. Selwyn-Clarke, *M.C.* (Gray's Inn).

THE advance programme of the twenty-second Voyage d'Études Médicales in the French Alps has been issued, and an outline of the programme may be useful to those whose circumstances necessitate the determination of their holiday arrangements early in the year. This year's tour will take place in the first fortnight of September, and will be organized by Dr. Piery, professor of hydrotherapeutics and climatology in the Faculty of Medicine at Lyons, who will share the scientific direction with Professor Paul Carnot and Professor Maurice Villaret. After visiting the Faculty at Lyons the party will assemble at Vals; from Briançon the members will travel by Alpine autocars through the Briançon district, the Dauphiné, and Savoy, visiting various health resorts and spas en route, to Evian, where the tour will terminate. The complete programme, with details regarding conditions of membership, etc., will be available about Easter. Inquiries should be addressed to Madame Juppé-Blaise, Federation of the Health Resorts of France, 1, Gordon Square, London, W.C.1.

PROFESSOR CLEMENS PIRQUET, director of the University Children's Clinic at Vienna, has been awarded the Aronson prize for his work on hypersensitiveness.

The following appointments have recently been made in the Italian faculties of medicine: Dr. A. Contino of Bari, professor of clinical ophthalmology at Messina; Dr. M. Bolaffio of Cagliari, professor of obstetrics and gynaecology at Modena; Dr. L. Torraca of Sassari, professor of surgical pathology at Padua; Dr. F. Ravenna of Turin, professor of morbid anatomy and histology at Perugia; and Dr. F. Spirito, director of the obstetrical school at Novara, professor of obstetrics and gynaecology at Siena.

DR. J. BORDET has been elected president of the Royal Academy of Medicine of Belgium for 1929, with Dr. M. Herman of Mons and Dr. J. Demoor of Brussels as vice-presidents.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediserra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

HOLIDAY INTERCHANGE FOR DOCTOR'S DAUGHTER.

A FRENCH doctor's daughter, aged 18, and living at St. Palais-sur-mer, Charente Maritime, desires to spend her holidays in England, and would like to effect an exchange with an English doctor's daughter who wishes to visit France. Applications should be addressed to Miss Hilda Fox, International Society of Medical Hydrology, 139, Marylebone Road, W.1.

TREATMENT OF RHEUMATIC HEART DISEASE.

"X. Y. Z." would be glad to have suggestions as to treatment of a boy, aged 14, who has been in bed for ten months with cardiac rheumatism. His present condition is good, and there are no *rheumatic pains; the pulse is regular and the rate is* 100. The heart is hypertrophied and there is a *loud mitral* systolic murmur. The patient has been kept in bed on account of a *persistent temperature of* 98.4° to 99.4° F.; *there is reason to* believe the infection arises from an unhealthy throat. Is tonsillectomy or vaccine treatment to be recommended?

INCOME TAX.

Untaxed Income: Personal Allowances.

"M. E." has retired from practice, having a private income of about £500 per annum. Tax is deducted at the source, except in respect of £20 War Loan interest and as regards the annual value of his freehold house £32. Should he make any "return" of his income.

*** On the facts "M. E." can claim repayment as follows—

On £135—(£20 + £32=) £52; that is, £83 at 4s. =	£16 12 0
And on £225 at 2s. ... ... =	£22 10 0
	£39 2 0

for 1928–29 and previous years. We suggest that he should take *an early opportunity of calling at the office of the local inspector* of taxes to explain the facts and obtain the necessary repayment *claim forms. Seeing that he owes no tax—in fact, the reverse is* the case—we do not see how there can be any "bother" caused by his not having made a return of his untaxed income.

Expense of Rent, Rates, etc.

"R. H. P." inquires as to the proportion allowable as professional expenses; he was allowed two-thirds until recently, when the proportion was reduced to one-half. The total amount of rent and rates is £107, and covers consulting and waiting rooms on the ground floor and partial use of other rooms.

*** We cannot advise an appeal against the allowance of one-half of the £107. That leaves £53 10s. to cover the rent and rates on the private portion of the premises, which does not seem unreasonable. The amount of "R. H. P.'s" non-professional income is not relevant.

LETTERS, NOTES, ETC.

BIOCHEMICAL CHANGES IN ALLERGIC PATIENTS.

DR. J. ANDERSON (Glasgow) writes: With reference to the interesting paper by H. W. Barber and G. H. Oriel on biochemical investigations in allergic conditions on November 17th (p. 880), the following notes of the biochemical changes in an asthmatic woman, aged 28, observed over a prolonged period, may be of interest. In this case twenty-four-hour specimens of urine were examined at frequent intervals. Attacks of asthma occurred generally at the week-end, and were preceded by constipation; she suffered also at menstrual periods. She had premonitory symptoms before the attack commenced, and evidence of an impending attack was shown by a higher specific gravity of the urine, a deposit of urates, a fall in *p*H, and the appearance of indican, with a trace of acetone. In the urine the specific gravity and acidity varied with the severity of the patient's symptoms, corresponding variations occurring throughout the investigation. The *p*H was lowest and the specific gravity highest at the onset of an acute attack. Preceding the attack the *p*H fell and the specific gravity rose; succeeding the attack the *p*H rose and the specific gravity fell. Albumin appeared, [illegible] fall in diastase and associated with a higher fall in *p*H, and increased acetone. When this was associated with a rise in diastase, and its reappearance was associated with a fall in the diastase content. A decrease of indican occurred with a second rise of diastase. The gradual improvement of the patient was associated with a fall of the specific gravity, a change in the deposit, and the disappearance of acetone. These results indicate that metabolic changes are present not only during the actual asthmatic attack, as shown by H. W. Barber and G. H. Oriel, but also for several days or weeks before the onset of the attack. This view has long been held by Dr. James Adam of Glasgow, and the investigation was made as an attempt to substantiate it.

HERNIA AND EVENTRATION OF THE DIAPHRAGM.

MR. A. P. BERTWISTLE (London, W.) writes: In your issue of December 1st, 1928 (p. 985), Dr. J. L. Thomas described an excellent case of diaphragmatic hernia, but under the title is the word evisceration; surely evisceration means disembowelling, a routine procedure in abdominal surgery before we learnt to have respect for the peritoneum. The term meant is eventration, and yet this, too, is wrong. Eventration is said to exist when the diaphragm has an unduly high dome; it may be congenital or due to trauma. The feature which differentiates it from hernia is that the diaphragm moves normally with respiration. Hernia has the same origin as eventration; it occurs almost always at the site of the embryonic pleuro-peritoneal passage and on the left side, pushing the heart over to the right. Its chief characteristic is that while the diaphragm moves downwards in inspiration, the stomach moves upwards, as shown radiographically by its air bubble. Carman aptly terms it "paradoxical respiration." See *Surgical Radiology*, by A. P. Bertwistle (p. 121).

SACRO-ILIAC MANIPULATIONS.

DR. EDGAR CYRIAX (London, W.) writes: In your report of the discussion of sacro-iliac pain by the Medical Society of London (December 22nd, 1928, p. 1137) one speaker is said to have expressed the opinion that complete anæsthesia of the patient is necessary before performing manipulation of the sacro-iliac joint. I have not found general anæsthesia essential in the vast majority of cases. The necessary relaxation can be obtained by preliminary vibrations and certain special passive movements which I have elaborated. I have reduced over 1,500 cases of subluxation of the ilium without the use of general anæsthesia, and at the most have merely caused the most transient and mild sensations—never any real pain. When an iliac subluxation is reduced in children the patients very frequently take no notice whatever of the bone having been moved.

KALA-AZAR IN CHINA.

DR. UPENDRANATH BRAHMACHARI (Calcutta) writes, with reference to a review of his book, *A Treatise on Kala-azar*, which appeared in the *British Medical Journal* of September 29th, 1928 (p. 572), to point out that he gave a full account of the work on the disease in China in the addendum, and that the reviewer's statement that "little is said of the disease in China" therefore requires amendment.

THE HIPPOCRATIC OATH.

WE have received from Mr. John Bensley Thornhill (77, Bedford Gardens, W.8) a blackwood panel, with bevelled edges, on which extracts from the Hippocratic oath, rendered into appropriate English, have been incised in white lettering. The panel rests on a small blackwood stand, and may conveniently be placed on the doctor's table. The price of the panel is 12s. 6d., and of the stand 1s. 6d.

HISTORY OF MANCHESTER.

WE have received from Dr. E. M. Brockbank the following note concerning his interesting article on the history of Manchester published in our issue of January 26th at page 167. "I find in my account of the history of Manchester in the current number of the *Journal* that I have, by an unaccountable slip, put cotton towns into West Cheshire, whereas they are in a curious easterly cur-tailed invasion of S.W. Yorkshire by Cheshire."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 21.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

105. Clinical Sequels of Untreated Syphilis.

S. DAHLSTRÖM (*Norsk Mag. f. Lacgevid.*, October, 1928, p. 16) states that the most common estimate of the frequency with which syphilitic patients develop general paralysis is about 4 per cent. As an old pupil of Professor Caesar Boeck, who taught that the so-called specifics, potassium iodide and mercury, were injurious because they not only failed to eradicate the disease, but also forced it into unnatural channels, provoking general paralysis of the insane and other serious lesions of the central nervous system and the blood vessels, Dahlström has been on the look out for paretics among Boeck's old patients, but has found hardly any. Among the 320 cases of general paralysis treated at the psychiatric department of the Ullevaal Communal Hospital in Oslo, only two were found to have been treated on Boeck's "wait and see" lines. Even in these two cases there was a possibility that mercury had been given elsewhere. It is also noteworthy that tramps and those who evade systematic specific treatment, and the coloured races living under primitive conditions at home, seldom develop general paralysis, whereas it is comparatively common in negroes living in centres of civilization where they are given specific remedies. E. BRUUSGAARD (ibid., December, 1928, p. 1222) has traced and re-examined 230 of the 2,181 patients suffering from primary and secondary syphilis who were under the care of his predecessor in the chair of dermatology in the University of Oslo, Professor Caesar Boeck, from January 1st, 1891, to December 30th, 1910. Added to these survivors were 164 patients, belonging to the same period, the causes of whose deaths were known. In addition to the total of 230 surviving patients whose disease dated back to 1910 or later, there were 79 who belonged to a later period, but who had this in common with the patients of the older group, that they had not received specific treatment. Boeck's reason for withholding mercury and potassium iodide from nearly all his patients was his belief that this treatment merely suppressed the outward manifestations of the infection, encouraging it to assume serious and atypical forms, because they interfered with the natural processes of immunity. He considered that tinkering with mercury and potassium iodide was largely responsible for such diseases as general paralysis and tabes. Brunsgaard's re-examinations of Boeck's old patients were started in 1925 and continued in 1926 and 1927. A thorough examination was made of the heart, and skiagrams were taken in two planes. In addition to a routine neurological examination, the Wassermann test was performed on the blood in almost every case. It was found that 131 patients showed a negative Wassermann reaction and were without any clinical signs of the disease; 70 were also without any clinical signs, but they had a positive Wassermann reaction. There were 67 (some alive and others dead) showing signs of disease of the blood vessels; 13 had developed general paralysis, and 6 tabes. As most patients with general paralysis drift into asylums, and as Brunsgaard has searched the records of the asylums in the area under review, it is probable that the 13 cases of general paralysis were very near the total of the patients who developed this disease out of the 2,181 attending Boeck's clinic. In other words, the incidence of general paralysis in this material was only 0.6 per cent. The problem was somewhat different in the case of the 6 patients with tabes (0.27 per cent. of the total), for many abortive forms of tabes are never diagnosed, only the typical and advanced cases coming to hospital. Brunsgaard comments on the fact that a very considerable proportion of the syphilitics who receive no specific treatment ultimately recover from it by virtue of their own inherent powers of resistance; and he emphasizes the importance of promoting these forces by means of non-specific remedies, such as infection with malaria. He does not, however, attack modern specific treatment.

106. Primary Achlorhydria.

DRAWING a distinction between achlorhydria and the condition of achylia in which there is an absence not only of free hydrochloric acid but also of the gastric ferments, J. P. SCHNEIDER and J. B. CAREY (*Journ. Amer. Med. Assoc.*, December 8th, 1928, p. 1763) divide 93 cases of achlorhydria studied during the past seven years into primary and secondary types. Various causes, such as gastric cancer and syphilis, may produce a secondary achlorhydria, and 42 of the cases fall into this group, while the remaining 51 were apparently primary. Four explanations for this primary condition have been suggested. The authors agree with the one advanced by Hurst, who maintains that true achylias are probably constitutional glandular deficiencies; the achylia of pernicious anaemia is not only constitutional, but actually hereditary and familial. In support of this hypothesis they state that in the series of 51 cases 6 had family histories showing that other members had this condition by the occurrence of pernicious anaemia, and in a series of 112 pernicious anaemia cases 6 positive and 6 suggestive histories were found. Thus a positive history of pernicious anaemia was found in 12 per cent. of the cases of primary achlorhydria and in from 6 to 12 per cent. of the true pernicious anaemia series. Arnoldi and Schlecter have endeavoured to prove that gastric achylia is constitutional, and simply a part of a functional deficiency including the liver, pancreas, and stomach. The authors conclude that there is a primary achlorhydria existing in certain individuals which is probably due to some constitutionally defective factor, and shows a definite hereditary and familial tendency. Demonstrable symptoms may not arise for many years, but several of such persons show certain historical and physical data which indicate that they may develop an idiopathic pernicious anaemia. The condition of achylia exists for many years before other indications of the haemolytic anaemia are evident. The authors add that when a history of recurring glossitis and achlorhydria is found there is every reason to suspect idiopathic pernicious anaemia, regardless of the blood picture.

107. The Argyll Robertson Pupil in Epidemic Encephalitis.

R. J. HARTER (*Thèses de Nancy*, 1927-28, No. 376), who records twelve illustrative cases, maintains that the Argyll Robertson pupil, which has hitherto been regarded as pathognomonic of syphilis, is rather an indication of any kind of involvement of the iridomotor apparatus. The lesions capable of producing it have their seat of predilection in the mesencephalon and ciliary ganglion. There is no special period for the appearance of the sign, which may first develop at the onset or in the early stage of the post-encephalitic syndrome. In most cases in which the Argyll Robertson pupil is present there is no question of encephalitis, but in those in which there is doubt as to whether the condition is one of encephalitis or nervous syphilis, the presence of this sign should now no longer be regarded as conclusive of syphilis.

Surgery.

108. The Psoas in Hip Affections.

J. GOURDON (*Presse Méd.*, January 2nd, 1929, p. 3) emphasizes the importance of muscular contraction or retraction in cases of congenital dislocation of the hip and also inflammatory lesions. According to him the influence of the adductors, sartorius, and tensor fasciae femoris is well realized, but that of the psoas is often overlooked. This influence is particularly marked in congenital dislocation, and more especially when it is bilateral; the lordosis with a large curvature or "high lordosis," consequent on tipping forward of the pelvis by a contracted psoas, so often found in cases recognized late, can easily be distinguished from the lordosis due to backward displacement of the femora, because the latter disappears after reduction, whereas the former does not. The psoas contraction does not hinder reduction, but by maintenance of forward tipping of the pelvis, and a certain degree of flexion and external rotation of the femur, favours recurrence of the dislocation; and even if it is insufficient to give rise to recurrence, it causes persistence of lordosis and a faulty position of the limb in external rotation. Gourdon remarks that in inflammatory affections of the hip lordosis and external rotation of the limb, coming on early with the adduction, are traceable to psoas action, and he attributes to this also the pain, so often experienced by subjects of hip disease, in the lumbo-dorsal region. In young patients where the contraction is moderate, he recommends treatment by strapping to a flat surface for an hour a day, with bands round the thighs, thorax, and the abdomino-pelvic region; in the slighter cases it may be sufficient to extend the lower limbs, at the same time maintaining pressure backwards at the level of the anterior part of the pelvis. The wearing of a retentive corset to maintain the corrected position may be necessary in after-treatment. In older patients tenotomy of the psoas insertion may be necessary, but Gourdon warns operators not to expect to obtain always an immediate

correction of the lordosis, since long-continued psoas contraction provokes periosteal reactions sufficient to cause adhesion of the muscle itself in the region of the ileo-pectineal line; careful orthopaedic after-treatment alone can overcome the residual deformity.

109. Surgery of Malignant Tumours of the Bladder.

ACCORDING to V. C. HUNT (*Journ. Amer. Med. Assoc.*, December 1st, 1928, p. 1704) epithelioma is the predominating malignant lesion of the bladder, and comprises 95 per cent. of such lesions. The degree of malignancy varies, and Broder's classification is recommended as being a guide to treatment and prognosis. According to this classification tumours are divided into grades 1 (the least malignant), 2, 3, and 4; more than half the recorded cases show a high malignancy and are placed in grades 3 and 4. The site of the tumour appears to have a bearing on its malignancy, those of the base being more malignant than those of the lateral walls or dome. Hunt enumerates various palliative surgical measures, but discusses more fully curative operations. Operations for tumours of the lateral and posterior walls and dome and of the base are described; and since the latter necessarily involve displacement of the ureter, the relative merits of ureteral tying and reimplantation are compared. The value of surgical diathermy is discussed, and also prophylactic measures for the prevention of recurrences. The results of surgical procedures depend on the site, extent, and degree of malignancy of the tumour, the magnitude of the operation, and, in lesions of the base of the bladder, on the method of disposing of the ureter. The mortality is lowest following the excision types of operations on the lateral walls and dome, and highest in segmental resections for tumours of the base with reimplantation of the ureter. Division and tying of the ureter has proved the best method when this organ is involved in the lesion or in operations for extensive tumours of the base. Hunt reports that, of 370 patients with epithelioma of the bladder, approximately 65 per cent. of those graded 1 and 2 are living and well three years after operation; equally good results have been obtained in approximately 35 per cent. of the cases graded 3 and 4. He believes that, although all cases cannot be cured, a higher percentage of good results may be obtained by surgical than by any other method.

110. Tuberculosis of the Finger.

M. BENCI and A. MEZZARI (*La Chir. degli Organi di Movimento*, October, 1928, p. 57) discuss tuberculosis affecting the finger, and report 68 cases of its occurrence in a sanatorium. They found that tuberculosis of the finger was present in 4.2 per cent. of the osteo-articular cases, and appeared mainly in early infancy. There was a history of hereditary tuberculosis in as many as 54.4 per cent., and the finger infection was often associated with other tuberculous manifestations (66 per cent.), especially of the lymphatic glands. Trauma in the previous history was exceptional (4 per cent.). Monophalangeal localization was common (52.9 per cent.), followed later by localization in other fingers; the hand was much more often attacked (89 per cent.) than the foot, and the proximal rather than the distal phalanges. Fistula occurred in 75 per cent. The lesion may be osteo-periosteal (more commonly in children) or central, the form more often seen in adults. Cure was obtained in 73.54 per cent. of the cases. The mean duration of the disease was eighteen months, and of the treatment eleven months. Subsequent deformity was noted in 31 per cent. of the cases. Active surgical treatment was confined to removal of sequestra, and rigid immobilization was employed only in cases where the joints were affected.

111. Treatment of Perforated Gastro-duodenal Ulcers.

GUILLEMINET and LATREILLE (*Lyon Chir.*, November-December, 1928, p. 782), giving the results of 44 cases operated on for perforated gastric or duodenal ulcer, call attention to the increasing frequency with which this condition occurs, there having been only 5 cases in 1924, 7 in 1925, 13 in 1926, 11 in 1927, and 8 in the first six months of 1928. In the majority of cases operation was undertaken within five to eight hours after perforation, owing to early diagnosis. In 41 cases the perforation was sutured, a gastro-enterostomy being usually performed, with suprapubic drainage, in many cases. One patient was treated by pylorectomy and two by packing with gauze and a gastro-enterostomy. Out of the 44 cases there was a mortality of 5, or a little more than 11 per cent. Two of these five patients did not come for operation until too late, the delay being in one case twenty-six and in the other thirty-six hours after the perforation. A third patient died on the sixth day of secondary peritonitis, and another in the third week owing to gangrene of the lung. Out of the 39 successful cases, only 2 patients required further surgical treatment; in 18 cases the result was so good that the patients were able to live a normal life without pain or discomfort.

Therapeutics.

112. Insulin Therapy in Non-diabetic Diseases.

R. MIGNOT (*Journ. de Med. et de Chir. Prat.*, December 10th, 1928, p. 859) quotes numerous cases recorded by various writers who claim that remarkable success has followed the administration of insulin in many affections of non-diabetic origin. Its mode of action in these cases is not yet understood, though it is known that insulin acts chiefly on carbohydrate metabolism, improves hydrocarbon combustion, combats acidosis, and also increases the protein metabolism. It has a definite influence on general nutrition, and influences the liver, kidneys, and the thyroid and suprarenal glands. It is recommended in the treatment of acidosis due to intractable vomiting of pregnancy, or to injury or surgical intervention. In a case of pancreatic fistula following duodenal ulcer Lafourcade found that insulin relieved a very serious condition. Infantile malnutrition has been treated successfully in America and France by the daily injection of 15 to 30 c.cm. of glucose serum per kilo of body weight, combined with 10 to 20 insulin units, in two to four injections; usually improvement is seen after a few days, but treatment must be continued for some time. There have been remarkable results also in cases of malnutrition in adults. Insulin administration relieves constipation and appears to increase alkalosis; its tonic action is incontestable, and it is indicated in emaciation associated with visceroptosis, asthenia, acidosis, endocrine disturbances, and tuberculosis. Its contraindications are rare, and include hyperpyrexia, especially when due to tuberculosis, diarrhoea, and haemorrhage. One writer recommends that the treatment should be suspended during menstruation. Some authors insist that patients should remain in bed under close observation during insulin treatment, and hypoglycaemia [illegible] against by giving at least 30 grams of [illegible] every meal. Dosage and method of administration vary considerably, but it appears advisable to commence with a total of 10 units daily during the first week, three doses being injected subcutaneously or intramuscularly fifteen or twenty minutes before the principal meals. This daily dosage is increased gradually during three or four weeks to 60 units or more. Successes have been recorded in cases of dry gangrene of the extremities or of the skin, in Raynaud's disease, and in a refractory case of angina pectoris. Several writers found insulin of great value in endarteritis obliterans and in various forms of severe anaemia, where it has been claimed that this treatment has been as successful as the administration of liver in pernicious anaemia. Insulin has been employed in catarrhal jaundice and other hepatic diseases; it relieves pruritus, and improves the appetite and general health. It is also recommended in certain psychoses—depressive, anxiety, and confusional—in delirium tremens, in menorrhagia of ovarian origin, and in amenorrhoea.

113. Treatment of Anterior Poliomyelitis.

G. R. KAMMAN (*Minnesota Med.*, December, 1928, p. 785) believes that human convalescent poliomyelitic serum is more efficient than Rosenow's antistreptococcal poliomyelitic horse serum. Both serums are highly specific in the treatment of acute infantile paralysis, and will immunize monkeys from the infection, but immunity does not last longer than six months. Early serum treatment gives better results, although recovery occurred in a case when the administration did not begin until two days after the onset of definite paralysis. In the acute stage rest and the routine treatment of all acute infections should be prescribed; repeated spinal draining is most important in relieving cerebro-spinal pressure. Kamman employs Bourne's method of administering the serum, 200 c.cm. of blood being collected in a sterile flask from a patient convalescent for some weeks from the disease, and free from syphilis and malaria; the blood is allowed to clot and the supernatant serum (usually about 75 to 100 c.cm.) is drawn off and kept in a cool place, with the neck of the flask plugged with sterile cotton. A dose of 15 c.cm. is injected intraspinally, and the same quantity is given intravenously on two successive days, spinal drainage being performed before each administration. If human convalescent serum is not available, Rosenow's serum may be injected intramuscularly after repeated spinal drainage. In addition to the serum treatment, massive doses of urotropine have been given; Bourne advises 10 grains every two hours until twenty-four doses have been given. The urine must be tested frequently, and urotropine discontinued if symptoms of renal damage appear. Urotropine may also be given as a prophylactic to children exposed to infection. When paralysis supervenes serum treatment is much less effective. The affected limb should be splinted to prevent malposition and contractures, and it should be wrapped in

wool, heat being applied by hot-water bottles and the therapeutic lamp. Absolute rest should be ensured, and sedatives and analgesics may be required. Gentle massage and passive movements are inadvisable during the acute stage, since too vigorous handling may damage the affected muscles irreparably. When large groups of muscles are involved the risk of weight-bearing should be deferred for a year or eighteen months.

114. Pituitary Extract in Diabetes Insipidus.

To avoid the necessity for repeated hypodermic injections of extract of the pituitary posterior lobe in cases of diabetes insipidus other less painful and more convenient methods have been devised, and J. R. CAMPBELL, jun., and H. L. BLUMGART (*Amer. Journ. Med. Sci.*, December, 1928, p. 769) have demonstrated that intranasal applications are as effective as injections. Eight cases of different etiology are reported in which the polyuria and polydipsia were effectively checked by this measure. Two intranasal methods are mentioned as practicable. In one, from 0.5 to 1 c.cm. of obstetrical pituitrin, which is half the strength of surgical pituitrin, is sprayed at three-, four-, or six-hour intervals into the nose so as to be deposited mostly on the roof of the nasopharynx. The second method, which is adopted by the authors, is application by means of a cotton swab. A pledget of absorbent cotton is soaked in 0.5 to 1 c.cm. of the extract, and is passed up one nostril towards the eyebrow. This is left in place till the next application, when it can be easily removed by blowing the nose. As a rule alternate nostrils are used. Emphasis is laid on the importance of inserting the pledget high in the nasopharynx. Occasionally a burning sensation is produced by the drug, but this usually passes off in a few days. In one case treatment had to be discontinued owing to intense nasopharyngeal irritation. This treatment can be as effectively applied by the patients themselves. The authors believe that the efficacy of the applications must be due to the continuous intranasal absorption of the drug over a long period of time, and that the absorption takes place through the lymphatics and not through the vascular routes.

Laryngology and Otology.

115. Hearing and Altitude.

F. D'ONOFRIO (*Arch. Ital. di Otol., Rinol. e Laryngol.*, October, 1928, p. 603) has made a series of observations of normal subjects and of those suffering from catarrhal deafness—in the first place at sea level, and secondly, at a height of about 5,000 ft. above sea level. He found that the normal person had a definitely greater acuity of hearing at the higher points than at sea level, and that the difference was even more marked in subjects suffering from catarrhal otitis media. The temperature was higher in the subalpine region than at sea level, but was as tolerable, or more so, owing to the dryness of the atmosphere. The humidity of the atmosphere at sea level is a factor which affects the middle ear and Eustachian tube, and reduces acuity. Another factor is the atmospheric pressure, which at 1,500 ft. is reduced to 714 mm. of mercury. The humidity and the pressure of the sodium chloride and the iodine in the air at the sea coast cause a hyperaemia and congestion of the Eustachian tube and middle ear. This congestion prevents the adjustment of balance between the air inside the middle ear and the outside air, and the effect of this on the ossicular chain and the insertion of the stapes into the wall of the middle ear is more marked at the higher pressure of sea level than in the subalpine districts. In the normal subject the hearing distance was increased by from 10 to 30 per cent. at the higher altitudes for the watch and for about the same for the voice. In the catarrhal cases the improvement was from 50 to 100 per cent. over that at sea level, and in these individuals there was a real improvement in the condition after somewhat prolonged sojourn at high altitudes.

116. Etiology and Treatment of Defects of Speech.

E. L. KENYON (*Journ. Amer. Med. Assoc.*, November 3rd, 1928, p. 1341) emphasizes the value of studying the movements of the thyroid cartilage during voice production, in order to obtain knowledge of the action of the extrinsic musculature concerned in speech, and, consequently, of the action of the vocal cords. He defines three independently controllable systems of muscles—namely, those of the chest; the oral and the extrinsic laryngeal muscles; and the intrinsic laryngeal musculature. He believes that abnormalities in sound production by the mouth and laryngeal muscles result chiefly from tension of those of the mouth which are under conscious control, and from the patient having only a crude psychological conception of the sounds to be produced. As the result of investigating cases in this way, Kenyon finds that methods of training of the speech mechanism for the correction of disorders of speech or of the voice may now be based on a more exact and complete psychological and physiological knowledge than has been possible hitherto. Operative procedures should not be contemplated until it has been shown that speech defects are not due to functional disorders. Kenyon describes how the movements of the thyroid cartilage during speech can be studied by finger palpation, and suggests that this should be employed more frequently before attempting to correct vocal abnormalities. He gives details of the anatomical considerations concerned.

117. Sinus Infections Due to Dental Caries.

G. BERRY (*Arch. of Oto-Laryngol.*, December, 1928, p. 698) believes that caries of the teeth is present in 60 to 80 per cent. of cases of maxillary sinus infections; these are more frequent in adult life than earlier, and a dental rather than a developmental etiology seems probable. Although dental abscesses may be revealed by radiography, yet in many cases the infection spreads quickly up to the antrum, arresting the bony resorption, and consequently its manifestation in the photograph. The rhinologist must therefore co-operate with the dentist and radiologist if the full extent of damage in any particular case is to be recognized. Recurring pains in the antrum on the side where a dead, or dying, tooth is situated should awaken suspicion that there is extension of the morbid process; similar importance is to be attached to an occasional seepage of pus from the middle meatus, small polypi in this region, and even a chronic unilateral nasal congestion without obvious explanation. The author believes that many a stubborn nasal and paranasal condition would yield to removal of an adjoining septic focus, such as a buried dental root.

Obstetrics and Gynaecology.

118. Pregnancy associated with Cervical Cancer.

IN cancer of the cervix complicated by pregnancy R. CONDAMIN (*La Gynécol.*, October, 1928, p. 578) thinks the therapeutic indications are clear if the pregnancy is near its commencement and the neoplasm is clearly operable, or, on the other hand, if the infant is viable and term is not far removed. In the first case speedy operation is called for, and the existence of pregnancy may be ignored; in the second case Caesarean section, followed by wide hysterectomy, should be performed if the cancer is operable, otherwise radium therapy is indicated. Another group of cases, however, those in which a pregnancy of three to six months' duration coexists with an operable neoplasm, has caused considerable difference of opinion; some surgeons advocate immediate operation with sacrifice of the foetus, while to others continuance of foetal existence appears more important than the relatively small chance of maternal survival offered by radical hysterectomy in a patient who in nine out of ten cases is aged between 30 and 35. Condamin suggests that in the group of cases where treatment raises this problem a solution is to be found in the use of radium, followed in a majority of cases by Caesarean section towards term; at the same time he denies that the evolution of the pregnancy will be disturbed by adequate radium applications, or that the foetus will be injured. Reference is made to cases of radium treatment from the second to the seventh month of pregnancy; in three a Caesarean operation was done, in four premature birth occurred in the seventh to ninth months, and in four the infant was healthy and survived. That careful watching of the patient is required after the application of radium during pregnancy is shown by one of Condamin's cases, in which the patient, who neglected to return for Caesarean operation, succumbed to cervical tears produced in labour at the seventh month. One of Condamin's patients was in good health twelve months after radium treatment, during the fifth month, of a carcinoma confined to the anterior lip of the cervix; one of Pouey's patients was well three and a half years after similar treatment (at six months) of a more extensive tumour on the posterior lip. As a complement to radium treatment during pregnancy followed by Caesarean section, Condamin is inclined to prefer hysterectomy in cases in which the radiation has been given late (in the sixth or seventh month), and further radium applications are advised in cases in which the initial ones have been early or repeated.

119. Aschelm and Zondek's Test for Pregnancy.

I. ODESCALCHI (*Ann. di Ostet. e Ginecol.*, November 30th, 1928, p. 1347) reports the trial of Aschelm and Zondek's biological test for pregnancy in thirty patients. A negative reaction was found in only two cases of pregnancy; one patient was at term and the other had been delivered six days previously. The authors of the test state that the responsible hormone—that of the anterior lobe of the hypophysis—diminishes in the

urine towards term, and disappears on the eighth day after delivery. According to Aschеim and Zondek, their test gives positive results early in the first month after conception; in 250 cases of pregnancy 2 per cent. of errors occurred, and a like number of non-pregnant patients gave 1.6 per cent. of errors. The essential feature of the test is the detection in the patient's urine of a sufficient amount of the hormone of the anterior lobe of the pituitary body to induce, when injected into infantile white mice weighing 6 to 8 grams, intrafollicular haemorrhages and/or luteinization and formation of corpora atretica in the ovaries. Acid, filtered morning urine is injected subcutaneously in doses of 0.2 to 0.4 c.cm. six times in three days; the ovarian changes characteristic of a positive test can usually be recognized macroscopically after killing the animals. According to Aschеim and Zondek the ovarian hormone (folliculin), which is present in considerable amounts in the urine from the eighth week of pregnancy onwards, is not of importance in the test; besides being less abundant than the hypophyseal hormone, it is increased in the urine at the menstrual epoch and the climacteric. Aschеim and Zondek regard the pituitary hormone as the motor concerned in exciting ovarian activity; they found the pituitary to be the sole organ extracts of which, injected into infantile mice, produced a state of ovarian hyperfunction and oestrus, and they noted that pituitary extract (unlike ovarian extract) injected into castrated female mice was ineffective. None of Odescalchi's test cases was that of a pregnancy in the earliest months.

120. Scopolamine Anaesthesia in Labour.

BERTHA VAN HOOSEN (*Anesthesia and Analgesia*, November-December, 1928, p. 353) discusses scopolamine anaesthesia in the second stage of abnormal labour, refuting the general opinion that its use is contraindicated therein; she also considers the employment of hypodermic injections of scopolamine alone in contradistinction to the more general combination of scopolamine and morphine. The author's previous experience of 2,023 "twilight sleep" deliveries with an infant mortality of 2.3 per cent., a maternal mortality of 0.1 per cent., and analyses of stillbirths, asphyxias, and haemorrhages, are advanced in support of the view that scopolamine anaesthesia is safe in the second stage of normal and abnormal labour. In abnormal labour the advantages claimed for its use are freedom from exhaustion and fatigue for the patient; an economy in time should operative intervention become necessary; avoidance of interference with the natural uterine contractions; lessened trauma and loss of blood; and obviation in great measure of asphyxia of the infant, thus rendering resuscitation easier than when such a condition results from general anaesthesia. Notes of three cases of different types of abnormal labour are given to illustrate the author's contentions.

121. Tubo-uterine Implantation.

H. HEUCK (*Zentralbl. f. Gynäk.*, December 8th, 1928, p. 3145) alludes to five cases from the literature in which birth of a full-time child followed implantation of the divided Fallopian tube into the uterus. He reports a sixth case in a woman, aged 32, who had been married ten years, and was found, after four years' sterility following one childbirth and one abortion, to have tubes which were impervious to insufflation by the Rubin method. Laparotomy showed that both abdominal ostia were patent, but sounds were arrested at the thickened uterine ends. These were excised together with the isthmic portion; the tube walls were split dorsally, and the tubes were implanted in the region of their original attachment. Atresia was demonstrated microscopically in the excised portions. Fifteen months later a healthy child was born after normal labour at term. Heuck mentions also four other cases of conception following tubo-uterine implantation.

Pathology.

122. Therapeutic and Prophylactic Antityphoid Serum.

K. T. GLOUKHOFF (*C. R. Soc. de Biologie*, November 2nd, 1928, p. 1239) immunized rabbits and goats by intravenous injection during a period of four to six weeks of twenty-four-hour cultures containing 8 to 25 thousand million bacilli per cubic centimetre which had been previously submitted to the action of caustic potash and then neutralized by the action of acetic acid. The animals were bled two to three weeks after the last injection. The serum so obtained was tested on the rabbit by subcutaneous or intravenous injections at the same time as a lethal dose of typhoid culture containing 13 thousand million bacilli per kilogram. The dose of serum used varied from 2 to 5 c.cm., according to the weight of the animal. The control animals died in twenty-four hours, while those which had been given the serum survived after having a rise of temperature for two to five days. It was also found that the serum of normal rabbits or those immunized against other infections had no protective power. In immunizing goats their blood was mixed with endotoxin and injected directly into a vein. No anaphylactic shock was observed. The blood cultures of infected rabbits treated by serum remained sterile. Typhoid bacilli were found in the gall-bladder when the animals were killed. The serum, therefore, has an antitoxic action. Goat serum was employed intravenously in rabbits with infected lymphatic glands, the serum being injected from the second to the fifth day, when the temperature became normal for five to seven days, and then showed a slight rise for one to two days. The fall in temperature did not occur in control animals in which inoculation was not followed by injection of serum. Subcutaneous injection, even in very large doses, did not yield obvious results. As a general rule serum treatment after five days did not have any effect on the course of the infection. When the serum was given later the glands increased in size and sometimes became caseous, whereas early serum treatment lowered the temperature and protected the glands from more serious lesions. If the glands were excised before serum treatment, the temperature immediately fell after their removal. Examination for typhoid bacilli in the excised glands remained negative.

123. Embryonic Tissue Cultures.

K. HEIM (*Arch. f. Gynäk.*, June 26th, 1928, p. 250) gives a preliminary report of systematic endeavours, in which the Carrel-Harrison or Kuczynski technique was employed, to grow human embryonic, adult, and neoplastic tissues in a mixture of fowl and human serum to which extracts of human or fowl embryo had been added. Success is reported in the culture of spleen, heart, brain, skin, ovarian, and endometrial tissue, all from the human foetus; the tissue of placental villi could not be cultivated after the fourth month of foetal life, and no proliferation of syncytium was found to occur. Of adult tissues, culture of the peritoneum from pregnant subjects and of endometrium was found possible. Endometrial implants grew equally well whether taken in the menstrual, premenstrual, or intermenstrual phase; fragments from curetted specimens could be cultivated. No success was obtained, however, in cultures from endometrial fragments which did not include a segment of the basal layer. Decidual cultures succeeded up to the fourth month of pregnancy. Little or no evidence of growth was found in cultures from tumours.

124. The Thermostability of Agglutinins.

L. SILBER and NIKOLSKAJA (*Zeit. f. Immunitäts. u. exp. Therapie.*, November, 1928, p. 63) find that the agglutinins in a number of serums against such organisms as those of the typhoid, paratyphoid, dysentery, cholera, and proteus groups are destroyed by heating to 80° C. for one hour; but if the serum protein is prevented from coagulating, then the agglutinins remain to some extent intact. Bayer 205 was found to inhibit the heat-coagulation of proteins. When the serum was diluted to 1/10 in a 5 per cent. solution of this substance and heated, not all the agglutinins were destroyed. The amount remaining varied with different serums; as a rule the titre of the serum was reduced to about a quarter or an eighth of the original. The same protecting influence was manifested by weak acid. When one part of serum was mixed with two parts of N/10 HCl and seven parts of saline, so as to dilute the serum 1/10, the agglutinins were not completely destroyed by heating, except in one instance. Again, the explanation appears to be that weakly acid serum is not coagulated—at any rate completely—by the degree of heat used in these experiments.

125. Serum Changes in Kala-azar.

R. B. LLOYD and S. M. PAUL (*Indian Journ. of Med. Research*, October, 1928, p. 203) report a study of the serum changes in kala-azar before and during treatment, and refer to another article by themselves in the same journal in the previous July. They first examined the reaction which occurs when formalin is added to serum in cases of kala-azar, and concluded that, though the appearance of a white gel is not specific, it affords a very useful clinical test. In this disease an increase was shown to occur in the serum globulin content and of the euglobulin reaction, together with absolute decrease as regards the serum albumin. The authors found, by plotting curves for these changes, that a characteristic form was assumed, and they think that this indicates some deep-seated change during treatment. They believe that on these lines a serological standardization is made available for the control of treatment in kala-azar, comparable with the similar control of syphilis by the Wassermann test. They suggest also that a special euglobulin is present in kala-azar.

Reprinted from "The Practitioner" for January, 1929.

THE NEW GLAXO

(London: Glaxo, 56, Osnaburgh St., N.W.1.)

Although Glaxo as an infants' food has long been favourably known to every practitioner, the New Glaxo—the name given to Prescription (Humanised) Glaxo, with added vitamin D—marks, in view of the most recent researches in infantile dietetics, a decided advance on the older preparation.

In the past there has been a tendency to recommend high fat percentages in infants' foods, in an attempt to provide sufficient vitamin D to ensure calcium absorption and the prevention of rickets. This was known empirically long before vitamin D was recognised as a separate factor; but it often caused digestive disorders and defeated its own object.

The idea of excess of fat in infants' food is nowadays repudiated provided that sufficient vitamin D can be given, and the problem of providing this has been solved now that a non-fatty, tasteless concentrate of vitamin D, such as Ostelin (see *The Practitioner*, March, 1928, p. 207), is available. By the addition of Ostelin an adequate but not excessive quantity of fat can be given, which will not cause digestive troubles, and will eliminate constipation.

The New Glaxo, in our opinion, is an excellent conception, and shows that the manufacturers of infants' foods are not content to stand still, but are anxious to make use of new discoveries in scientific research.

Prescription Humanised Glaxo with added vitamin D (Ostelin) is popularly called "Sunshine Glaxo."

"Ostelin"

physiologically standardised vitamin D concentrate

IN FOUR EASILY ASSIMILABLE FORMS

Ostelin in Glycerin

("Ostelin")

In drop doses. 4 minims of the suspension are equivalent in vitamin D value to one drachm of cod-liver oil.

DOSE

Children: 1-4 drops t.d.s.p.c.
Adults: 2-10 „ „

Ostelin Tablets

("Tab. Ostelin Co.")

Each tablet contains the equivalent of a 4-minim dose of Ostelin with two grains of soluble calcium glycerophosphate.

DOSE

1 to 4 tablets t.d.s.p.c. As a prophylactic, 2 tablets twice daily

Ostelin Emulsion

("Emuls. Ostelin Co.")

Contains—Ostelin equivalent in vitamin D value to 50 per cent. of its volume of the purest cod-liver oil, together with calcium glycerophosphate.

DOSE

Infants: ½ teaspoonful 1 to 6 times daily.
Children: 1 teaspoonful t.d.s.p.c.
Adults: 1 to 3 teaspoonfuls t.d.s.p.c

Ostomalt

("Ext. Malti & Ostelin Co.")

containing vitamins A, B, C and D.

Each teaspoonful contains the equivalent of half-a-teaspoonful of orange juice with malt extract of high diastatic power.

DOSE

Children: ½ to 1 teaspoonful t.d.s.p.c.
Adults: 1 to 3 teaspoonfuls t.d.s.p.c.

Also

Ostelin Ampoules and Ostelin with Parathyroid Tablets.

For the Relief of Sacro-iliac Relaxation or Strain

WHETHER a sacro-iliac lesion has been caused by heavy lifting or pushing, bad posture, difficult childbirth, or by some other condition which tends to create abnormal tension in the muscles or ligaments of the sacro-iliac region, physicians usually deal with it by immobilizing the articulations involved.

Fixation of the sacro-iliac joints can be secured by use of a Spencer sacro-iliac corset or belt, designed with an inner band fitted with a pad which acts as a fulcrum in securing proper adjustment.

The sacro-iliac band which is built inside the corset or belt can be adjusted as tightly as necessary from the outside after the belt or corset is in place. Since the band is built into the Spencer support, it never rides out of position.

When the bony structure is held in position by the support, the bruised or strained ligaments are relieved of tension or pressure, and the return to normal condition hastened.

As the patient's condition improves, a light Spencer support, without the special sacro-iliac band, often can be substituted for the regular sacro-iliac support.

Each Spencer support is especially designed for the patient who is to wear it. The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue booklets on the use of Spencer Supports for the relief of sacro-iliac strain, hernia, enteroptosis, movable kidney, and for maternity wear. We will gladly send you any of them in which you are interested.

Spencer Sacro-iliac Belt

The belt shown in the illustration is designed from special measurements and figure description for the individual who is to wear it.

Spencer Sacro-iliac belts are made for both men and women.

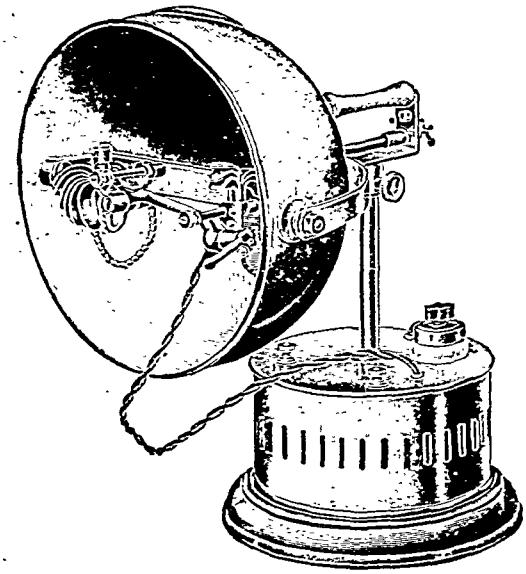
HAVE YOU fully realized the therapeutic value of Actino-Therapy and its wide range of application in YOUR PRACTICE?

THOUSANDS OF TREATMENTS ARE ADMINISTERED DAILY



"MEDISUN"
ULTRA-VIOLET LIGHT APPARATUS
100% BRITISH.

Specification:

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details.

RUNNING COST:

Thirty Treatments Threepence

PRICE:

For use on Direct Current £10 — For use on Alternating Current £18

THIRTY OTHER TYPES

Ask for Catalogue B42

Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

IMMEDIATE DELIVERY FROM STOCK. SOLE MANUFACTURERS:

MEDICAL SUPPLY ASSOCIATION, Ltd.

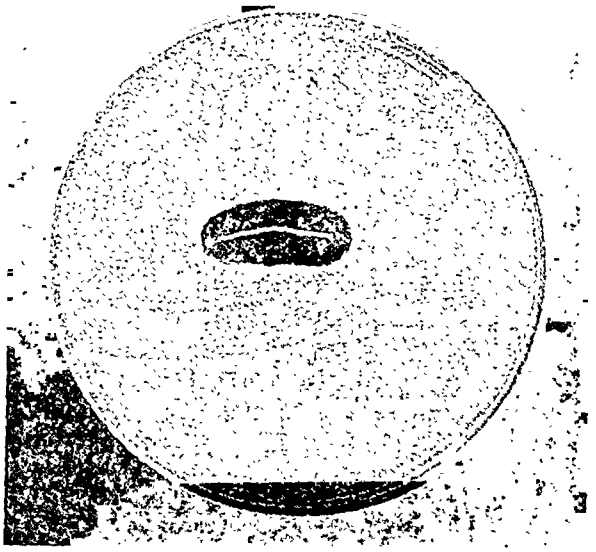
The largest X-Ray and Electro-Medical Showrooms in the British Empire

167-185, GRAY'S INN ROAD, LONDON, W.C.1

Telephone: Terminus 5432.

'ULTRATAN'
The LONDON HOSPITAL BINIODIDE CATGUT

(Morley's Process)



"A short length of London Hospital Biniodide Catgut was placed in agar-agar thickly sown with aerobic spores and incubated. The inhibiting action of Biniodide in the catgut not only prevented invasion but exerted a local bactericidal action in the infected agar-agar for a distance of from 5 m.m. to 9 m.m. round the ligature."

Members of the profession are invited to visit the department at the London Hospital, Whitechapel, to inspect the process of manufacture throughout.

A Sample and Descriptive Booklet will be sent post free on application to

ALLEN & HANBURYS LTD.
48 Wigmore Street, London, W1.

The London Hospital Catgut may be obtained from all the leading Surgical Equipment Houses

Every Doctor should know . . . .

that:

1. Rubber stockings are now out of date.
2. **Occulta Stockings,** the surgical stockings de luxe, are the very last progress in surgical hosiery. They are a boon to sufferers from varicose veins.
3. **Occulta Stockings** are comfortable, washable, rubberless, fashionable, invisible under the finest silk hose, and give the best support to the deficient vein tissue. Moreover, they have been fully approved and recommended by most prominent specialists of vein diseases.
4. **Occulta Stockings** are the only genuine stockings of that kind, made on scientific principles, and owing to their huge success many inferior imitations have been recently put on the market.
5. . . . that, by sending your address on a Post Card to—

"OCCULTA STOCKING,"
CROIX DE LORRAINE,
JERSEY, C.I.,

you will receive by return full particulars. *Ask for list of Agents.*

SURGICAL SERVICE
SALTAIR

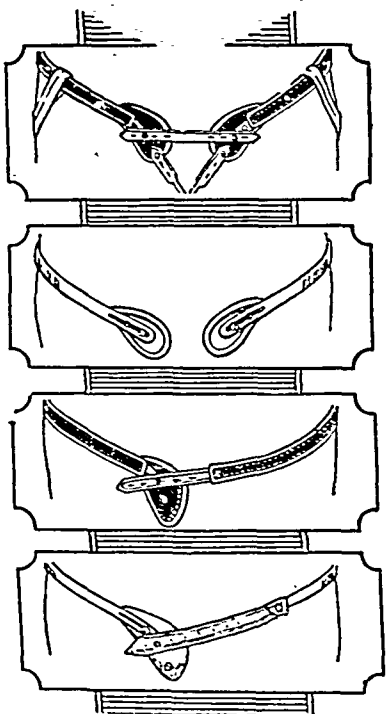
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

The Medical Profession with the aid of Salt's Surgical Service CAN (except in cases of gross carelessness on the Patient's part) PREVENT future cases of SEVERE HERNIA and greatly alleviate those already existing.



WHY ARE THERE SEVERE CASES OF HERNIA?

Every medical man will agree that severe Hernia is attributable to one or two causes:—

1. Neglect

whereby medical advice or surgical aid is not sought.

2. Fitting of Inefficient Appliances

The first case is beyond our control or that of the medical man until he is consulted. In the second case the patient either tries one of the much-advertised "Rupture Cures" or purchases a "Stock Truss," both of which are universal appliances—non-adjustable, and made to fit short, stout, tall, or thin—and, owing to inadequate support, the Hernia develops.

Out of more than 25,000 cases of developed Hernia personally fitted by us during the last 20 years, in the great majority of severe cases the history proved that the patients had obtained a "Stock Truss" or "Universal Appliance" in the first instance.

for their *DEAF* patients

Every important Medical Journal in the land has commended Mr. R. H. DENT'S world-famous aid for its efficiency and simplicity, and, if greater proof were required, it lies in the fact that

many DEAF DOCTORS use "ARDENTE"

"ARDENTE" STETHOSCOPE.—Mr. R. H. Dent also makes a stethoscope specially for members of the medical profession suffering from deafness, slight or acute. Many are in use, and excellent results are reported.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the *importance* of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of *uncertain effect.*

Vaporized Cresolene at night will be found a simple and effective means of preventing the *paroxysms at that time,* thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

THE POSTAL ACCOUNT
It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.
The Secretary of the Bank will be pleased to send a copy on application

METHODS AND USES OF

HYPNOSIS AND SELF-HYPNOSIS.

6s.

By BERNARD HOLLANDER, M.D.

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as detailed evidence of phenomena throwing light on the mysteries of thought-transference, clairvoyance, etc.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

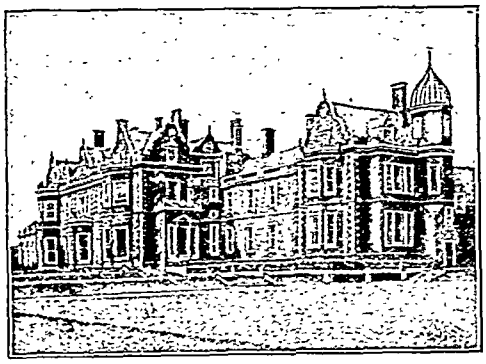
(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.



RENDLESHAM HALL.

To those desiring to be near London—
The Mansion, Beckenham Park, Beckenham, as carried on for the last twenty years, is available. Booklet and particulars from the Resident Medical Superintendent.

Telephone: RAVENSBOURNE 0648. *Telegrams:* NOROTORIUM, BECKENHAM.

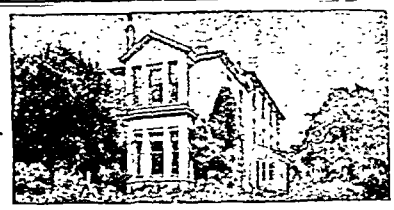
Proprietors: The Norwood Sanatorium, Limited.

ALCOHOLISM, DRUG HABIT, AND NEURASTHENIA.

BAY MOUNT, PAIGNTON.

(ESTABLISHED 1922) *'Phone:* PAIGNTON 5110.

This small comfortable Home is charmingly situated in secluded gardens overlooking Torbay. Ladies and Gentlemen treated with a view to a rapid and permanent cure by modern methods, which give excellent results. Ample amusement, billiards, wireless, golf, tennis, etc. Winter sunshine. Moderate inclusive terms. Prospectus, report, etc., from—
Stanford Park, M.B., Ch.B., Res. Med. Supt., Bay Mount, Paignton.



ALCOHOL AND DRUGS.

The SPRINGFIELD METHOD is unique in providing complete privacy and an intensive treatment of four weeks only. It was evolved, and is carried out, in a comfortable home in Hampstead, the address of which is never advertised.

"The Medical Annual" (1928) selects the Springfield Method of withdrawing drugs for special description.

Apply Medical Supt. (c/o 300, B.M.A. House, Tavistock Square, W.C.1).

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON
FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for *treatment. Careful clinical, biochemical, bacteriological, and pathological examinations.* Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a *Reception Hospital* in detached grounds, with a separate entrance, to which patients *and voluntary boarders can be admitted.* It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including *Turkish* and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche; *Electrical* baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every *facility for occupying themselves* in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, *amidst the finest* scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, *golf courses, and bowling greens.* Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, *such as carpentry, etc.*

For terms and further particulars apply to the Medical Superintendent (*Telephone*: No. 55 Northampton), who can be seen in London by appointment.

This Examination will commence on Monday, April 8th, 1929.

Students who have completed the required professional study and have fulfilled the other necessary conditions, and desire to present themselves for examination, must forward the necessary schedules through the post to the Examination Hall, Queen Square, Bloomsbury, London, W.C.1, fourteen days before the Examination commences.

HORACE H. REW,
February 1st, 1929. Secretary.

University of London.

A Course of Three Lectures on *"Electrical Phenomena in Muscle and Nerve"* will be given by Dr W. H. CRAIB, at UNIVERSITY COLLEGE, LONDON (Gower Street, W.C.1), on MONDAYS, FEBRUARY 4th, 11th, and 18th, at 5 p.m.

Admission free, without ticket

EDWIN DELLER, Academic Registrar.

Society of Apothecaries of LONDON.

MASTERY OF MIDWIFERY.

The next Examination will take place on Monday, May 20th, and following days. For regulations apply to—

FRANK HAYDON, Secretary.

Government of Southern Rhodesia.

PUBLIC HEALTH DEPARTMENT.

Applications are invited for the post of MEDICAL INSPECTOR OF SCHOOLS for the Colony of Southern Rhodesia. The official appointed will be attached to the Public Health Department. The commencing salary will be at the rate of £800 per annum, rising by £50 per annum to £1,000 per annum. Transport allowance for journeys undertaken on duty will be paid according to the Civil Service Regulations, and a commuted subsistence allowance will be paid at the rate of £150 per annum. Private practice will not be allowed.

The duties will include the medical examination of all school children, and, if necessary, all teachers, inspection of school premises, and the advising of the Government on medical and health matters pertaining to schools and school children. The appointment will be for a period of four years, and a contract will have to be entered into for that period. Salary will be payable from the date of reporting for duty in Salisbury, Southern Rhodesia. A passage will be provided to Salisbury, but this will not include the fare of any dependants.

The successful applicant must produce his birth certificate and satisfactory evidence of health, and should be between 30 and 40 years of age. He should have had previous experience in this class of work, and a qualification in Public Health, though not essential, will be considered an advantage.

Applications should be addressed to the Secretary, Office of the High Commissioner for Southern Rhodesia, Crown House, Aldwych, W.C.2, from whom any further particulars required can be obtained, and should reach that official before February 15th.

University of Lucknow.

Applications are invited for the PROFESSORSHIP OF MEDICINE and PHYSICIAN to KING GEORGE'S HOSPITAL, attached to the University. Salary Rs.1,200—50—1,400 per mensem, plus benefits of the University Provident Fund on confirmation (rate: 6 per cent. of salary paid by subscriber and 6 per cent. by the University). Consulting practice allowed. The selected candidate will be on probation for one year and will be required to join the Lucknow University about November 1st, 1929. Applications, stating age, academic qualifications, hospital experience, and research publications, with copies of three testimonials, should reach the Registrar, Lucknow University, Lucknow, on or before March 31st.

NOTE.—For members of the Indian Medical Service the conditions of service will be similar to those of Government servants holding similar appointments.

R. R. KHANNA, Registrar.

Wellington Hospital Board, NEW ZEALAND.

ORTHOPÆDIC SPECIALIST.

Applications from medical practitioners addressed to the undersigned, and endorsed "Orthopædic Specialist," are invited up to noon on March 31st, 1929, for the position of Orthopædic Specialist to the Wellington Hospital, at a commencing salary of £900, rising by two annual increments of £50 per annum to £1,000; non-resident.

The successful applicant will be required to undertake active treatment of fractures, to have practical experience of plaster technique, splint-making, and all branches of Physio-therapy—that is, Baineo-therapy, Electro-therapy (including Ultra-violet) and Massage.

Applicants are requested to state age and qualifications, and to enclose copies of references.

R. BROWN, Secretary.

University of Melbourne, VICTORIA, AUSTRALIA.

CHAIR OF OBSTETRICS.

Applications are invited for the above Chair. Salary £2,000 per annum. For particulars apply to the Agent-General for Victoria, Victoria House, Melbourne Place, Strand, London, W.C.2, with whom applications must be lodged on or before March 31st.

Royal Alexandra Hospital for SICK CHILDREN, BRIGHTON.

(100 Beds.)

HOUSE SURGEON (male) required. Salary at the rate of £100 per annum, with board, lodging, and washing. Good experience, including Sun-Ray Treatment. No canvassing allowed. To commence duty on February 27th.

Applications, in writing, and accompanied by testimonials, should be sent to the Secretary, A. F. GRAVES.

The Hospital for Sick Children, Great Ormond Street, London, W.C.1.

A Whole-time ASTHMA RESEARCH SCHOLAR is required on February 21st, in the Asthma Clinic established at this Hospital, under the Halley Stewart Trust of the Asthma Research Council, for special research work in the causation and treatment of Asthma and kindred complaints in children.

Gentlemen are invited to send in their applications addressed to the Secretary, with copies of not more than three testimonials, written specially for the purpose, before 12 o'clock on Monday, February 18th.

The appointment is non-resident, and is made for one year, but may be held, subject to re-election annually, for a period of four years.

Candidates must possess a legal qualification to practise.

Salary £300 per annum, with luncheon and tea provided by the Hospital when on duty.

All candidates must be in attendance on Wednesday, February 20th, at 4.45 p.m. precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the rules may be obtained from the Secretary at the Hospital.

By Order of the Board of Management,
JAMES McKAY,
January, 1929. Secretary.

The Hospital for Sick Children, Great Ormond Street, London, W.C.1.

A CASUALTY OFFICER is required on February 21st.

Gentlemen must be registered medical practitioners, and are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, February 18th, accompanied by copies of not more than three testimonials, written specially for the purpose.

The appointment is made for one year, but may be held, subject to re-election annually, for a period of three years.

The appointment is non-resident, and whole-time.

Salary £400 per annum, with luncheon and tea provided, and allowance of 24 guineas for substitute for annual holiday of four weeks.

All candidates must appear before the Joint Committee at their meeting on Wednesday, February 20th, at 4.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary, at the Hospital.

By Order of the Board of Management,
JAMES McKAY,
January, 1929. Secretary.

Borough of Folkestone.

MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified gentlemen for the appointment of Medical Officer of Health of the Borough, subject to the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926.

The gentleman appointed will be required to perform all the duties imposed on a Medical Officer of Health, to act as Port Medical Officer of Health; Maternity and Child Welfare Medical Officer and School Medical Officer, and to carry out all such duties as the Council, with the consent (if necessary) of the Minister of Health, may from time to time direct, including the duties of Medical Inspector of Aliens if appointed to this post by the Minister of Health. He must devote all his time to the duties of the office and must not engage in private practice.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The salary to cover all the duties specified above will be £900 per annum inclusive.

Applications, accompanied by copies of not more than three recent testimonials, should reach the undersigned not later than February 16th.

Town Clerk's Office, C. F. NICHOLSON,
Folkestone. Town Clerk.
January 22nd, 1929.

Preston Union.

Applications are invited for the post of JUNIOR RESIDENT MEDICAL OFFICER.

Salary at the rate of £104 per annum, with board, lodging, etc.

Candidates must be duly qualified and registered under the Medical Acts.

The appointment is for six months commencing on March 1st.

Duties include work in any Wards of the Hospital, in the Institution as required, and also in the Sharoe Green Maternity Home adjoining.

Applications should be made by letter, accompanied by copies of three testimonials of recent date, and should reach me on or before 10 o'clock a.m. on Tuesday, February 5th.

Union Offices, THOMAS H. BENTHAM,
Lancaster Road, Clerk to the Guardians.
Preston. January 16th, 1929.

County Council of Durham.

EDUCATION DEPARTMENT.

ASSISTANT SCHOOL MEDICAL OFFICER.

The County Education Committee invite applications from duly qualified men for the post of Assistant Medical Officer to act under the School Medical Officer in connexion with the Inspection of School Children, and such other duties as may be required by the Education Committee. Commencing salary £600 per annum (provided the candidate has had not less than three years' post-graduate experience), rising by annual increments of £25 to £650 per annum, together with travelling expenses according to the County scale. The successful candidate will be required to devote his whole time to the duties of the office, and reside in or near the district to which he will be attached at a place to be approved by the Education Committee. The appointment will be subject to three calendar months' notice on either side, such notice to date from the last day of any calendar month. Applicants must have had experience in the work of school medical inspection, and preference will be given to candidates who:

(a) Have had experience in the work of School Clinics;
(b) Have been accustomed to make special reports on Mentally Defective, Physically Defective, Epileptic, and other Defective Children.

The possession of a Diploma in Public Health is desirable, though not essential.

Copies of not more than three recent testimonials are required.

Canvassing, directly or indirectly, is prohibited and will disqualify.

A deduction of 5 per cent. will be made from the salary in accordance with the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the County Council's medical examination in connexion therewith.

Forms of application, to be returned not later than Saturday, February 9th, may be obtained from the Director of Education, Shire Hall, Durham, on receipt of stamped addressed envelope.

Shire Hall, A. J. DAWSON,
Durham. Director of Education.
January 19th, 1929.

Parish of Willesden.

RESIDENT FIRST ASSISTANT MEDICAL OFFICER.

The Guardians invite applications for the appointment of Resident First Assistant Medical Officer (male) at Park Royal Hospital, Acton Lane, Willesden.

Salary £430, rising to £460 at the expiration of one year, with rations, furnished apartments, and laundry.

Candidates must be registered medical practitioners, and not under 30 years of age.

The officer appointed will be required to devote the whole of his time to the duties of the office, to administer anæsthetics, to give Lectures to the Nursing Staff, and generally to act under the supervision and direction of the Medical Superintendent. He will also be required to pay into the account of the Guardians all fees received by him, including fees for certifying lunatics, etc.

Forms of application may be obtained by sending a stamped addressed foolscap envelope to my office, as below, and must be returned to me not later than the first post on Monday, February 11th.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act.

By Order,
J. HUTTON HAYES,
Guardians' Offices, Clerk to the Guardians.
409, High Road,
Bloomsbury, N.W.6.
January, 1929.

13, Victoria St.,
Westminster, S.W.1.

States of the Island of Jersey.

COMMITTEE FOR THE JERSEY MENTAL HOSPITAL.

MEDICAL SUPERINTENDENT.

This office being vacant, the States will proceed next month to appoint a Medical Superintendent for the above establishment, who will be required to enter upon his duties about the end of February or beginning of March next.

The appointment is for three years, at a salary of £650 per annum, with house (and garden) in which the person appointed will be required to reside. The Medical Superintendent must devote the whole of his time to the duties of his office. Candidates must be Members or Licentiates of one of the Faculties of Medicine and Surgery of Great Britain or Ireland.

Sealed applications, stating qualifications, with testimonials, to be sent on or before February 9th, addressed to the President of the Committee for the Jersey Mental Hospital, Greffe Office, Jersey.

Greffe Office, Jersey. ERNEST LE SUEUR,
January 18th, 1929. Greffier.

Warwickshire County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from qualified and registered medical practitioners for the post of Assistant County Medical Officer of Health. The duties will include Medical Inspection of School Children.

The salary is at the rate of £600 per annum, and is subject to a deduction of 5 per cent. in respect of contributions under the Local Government and Other Officers Superannuation Act, 1922. In addition, motor car allowances in accordance with the Council's scale and reasonable travelling expenses are paid. The appointment is also subject to the production of a medical certificate satisfactory to the County Medical Officer of Health. Preference will be given to one who holds a Diploma in Public Health

Forms of application and statement of the duties and terms of the appointment can be obtained from the undersigned. Applications (marked "Assistant County Medical Officer of Health"), with copies of not more than three recent testimonials, must be received by me not later than Monday, February 11th.

Canvassing, directly or indirectly, will be considered a disqualification.

42, Warwick St., L. EDGAR STEPHENS,
Leamington. Clerk of the County
January 22nd, 1929. Council.

Swansea County Borough.

RESIDENT MEDICAL OFFICER.

INFECTIOUS DISEASES HOSPITAL.

The Council invite applications for the above appointment from duly qualified unmarried medical practitioners. The salary will be at the rate of £350 per annum, together with emoluments. Previous experience in an Infectious Disease Hospital is desirable.

Applications (on special forms with particulars of duties, can be obtained from the Medical Officer of Health, Public Health Offices, Swansea) to be sent in not later than February 13th.

Metropolitan Asylums Board.

The Board invite applications for the appointment of ASSISTANT MEDICAL OFFICER (JUNIOR) at THE DOWNS HOSPITAL FOR CHILDREN, SUTTON, SURREY (360 beds). Salary £500 per annum. Must be a good operator for the removal of tonsils and adenoids, and preferably with some experience of diseases of the ear. The candidate appointed will be required to reside in the Hospital, and to pay for board, lodging, and washing at the rate (at present £130 per annum) fixed from time to time.

Form of application may be obtained by sending stamped addressed foolscap envelope to the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4, by whom completed applications must be received not later than 10 a.m. on February 11th.

ALLAN POWELL,
Clerk to the Board.

Tyrone County Hospital, Omagh.

The Committee of Management of above Hospital will, at their meeting on Tuesday, February 19th, appoint a HOUSE SURGEON, with knowledge of Radiology, for a period of six months.

Applications stating age, qualifications, and experience, with copies of not more than three testimonials, to be forwarded to the Registrar on or before Thursday morning, February 14th.

Salary £100 per annum, with board and lodging.

County Borough of Smethwick.

SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council invite applications from qualified medical men for the position of Senior Assistant Medical Officer of Health.

Salary £550 per annum, with furnished residence for single man at the Isolation Hospital, Holly Lane, including lighting, heating, board, and laundry. If a married man is appointed the salary will be £700 per annum, without board and residence.

His duties will be to act as Medical Officer at the Isolation Hospital, to work at the Tuberculosis Dispensary and School Clinics on certain days, and to carry out a certain amount of School Medical Inspection.

Applicants must be registered medical practitioners, and should possess the Diploma of Public Health.

The officer appointed will also be required to assist the Medical Officer of Health in his other duties from time to time as directed, and will work under the general supervision of the Medical Officer of Health.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned, to whom applications, endorsed "Assistant Medical Officer of Health," and accompanied by copies of three recent testimonials, must be delivered not later than February 14th.

Canvassing, directly or indirectly, will disqualify.

Council House, FRANK CHAPMAN,
Smethwick. Town Clerk.
January 29th, 1929.

County Borough of Ipswich.

ASSISTANT MEDICAL OFFICER OF HEALTH (Woman).

The Corporation of Ipswich invite applications for the appointment of an Assistant Medical Officer of Health and Assistant School Medical Officer.

Applicants must be fully qualified medical practitioners, and must hold a Diploma in Public Health, or an equivalent qualification.

Applicants must be qualified to undertake ante-natal and infant welfare work.

Experience in Mental Deficiency, and in Ultra-violet Ray Treatment, would be regarded as additional qualifications.

Salary £600 per annum.

The successful candidate will be required to contribute to any Superannuation Fund which the Town Council may establish.

The person appointed will be required to devote her whole time to the duties of the office, and to act under the control of the Medical Officer of Health, who is also School Medical Officer.

The duties of the position will be mainly concerned with the School Medical Service, but the Public Health Committee retain the right to utilise the services of the person appointed as may be required by them.

Applications, together with copies of not more than three recent testimonials, to reach the Medical Officer of Health, Elm Street, Ipswich, not later than February 16th.

Town Hall, A. MOFFAT.
Ipswich. Town Clerk.
January 29th, 1929.

Charing Cross Hospital, PHILIP INMAN,
Strand, W.C.2. House Governor.

WEST AFRICAN MEDICAL STAFF

VACANCIES exist for MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH in the BRITISH WEST AFRICAN COLONIES.

SALARIES.

Medical Officers receive salaries at the rate of £660 a year, rising by annual increments of £30 to £720 a year, and then on confirmation £720 a year, rising by annual increments of £40 to £960 a year, together with a seniority allowance (payable only in West Africa) at the rate of £72 a year. After three years' service on £960, the salary may be raised to the scale of £1,000 a year, rising by annual increments of £50 to £1,150 a year, together with a seniority allowance at the rate of £100 a year.

Medical Officers of Health receive salary on the above scale beginning at £800 a year, together with seniority allowance of £72 a year. They also draw staff pay at the rate of £150 a year, half of which is payable during leave.

QUARTERS.

Free furnished quarters are provided or an allowance in lieu.

OUTFIT ALLOWANCE.

An outfit allowance of £60 is granted on first appointment.

PASSAGES.

Free first-class passages are provided on first appointment, and when proceeding on or returning from leave.

PENSIONS.

All appointments are pensionable; a minimum service of seven years is required to qualify for a pension. An officer may retire on reaching the age of 50 and may be called upon to retire at the age of 55. Officers of the West African Medical Staff are permitted to retire if they wish with a gratuity of £1,000 or £1,250 after nine or twelve years' approved service respectively, but in that event they receive no pension.

TOURS OF SERVICE AND LEAVE.

A tour of service in West Africa lasts from twelve to eighteen months at the discretion of the Colonial Government, and is followed by leave at the rate of one week for each completed month of residential service. Leave begins on the date of arrival in England.

PROMOTION.

There are good prospects of promotion in the West African Medical Staff.

COURSE OF INSTRUCTION.

Selected candidates are required to attend courses of instruction in tropical medicine and hygiene at either the London School of Hygiene and Tropical Medicine or the Liverpool School of Tropical Medicine or the University of Edinburgh.

Further information regarding the conditions of service, pensions, etc., may be obtained from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, to whom applications should also be addressed.

MALAYAN MEDICAL SERVICE

APPOINTMENTS

VACANCIES exist at present for MEDICAL OFFICERS in the MALAYAN MEDICAL SERVICE. Candidates, who should be British subjects of European parentage and not over 35 years of age, should apply to the PRIVATE SECRETARY (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, for the necessary form of application. Preference is given to candidates who have held Hospital appointments as House Surgeons and House Physicians. Selected candidates are required to attend one of the Schools of Tropical Medicine, the fees for their tuition being defrayed by Government, and an allowance paid during their instruction.

SALARIES.

2. The initial salary of a Medical Officer is $500 per mensem (£700 per annum), rising by annual increments of $25 per mensem (£35 per annum) to $550 per mensem (£770 per annum). Officers are appointed on probation for a period of three years and then become eligible for confirmation, after which the salary rises by annual increments of $25 per mensem (£35 per annum) to $800 per mensem (£1,120 per annum).

ALLOWANCES.

3. In addition to salary, there is at present a temporary allowance of 10 per cent. of salary to unmarried officers and 20 per cent. to married officers. A non-pensionable allowance of $100 per mensem (£140 per annum) is paid to officers holding the Diploma in Public Health.

CURRENCY.

4. The Straits dollar is equivalent to 2s. 4d. of English currency. The rate is liable to alteration, but has remained unchanged for many years past, and so far as can be foreseen no change is anticipated.

PASSAGES.

5. Free first-class passages are provided on first appointment and on leave.

QUARTERS.

6. Quarters are usually available and are provided at a rental which in no case exceeds 6 per cent. of the officer's salary.

PRIVATE PRACTICE.

7. Private practice is not allowed, but consultation with another practitioner is permitted.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880.)

12, Stratford Place, Oxford Street, W.1.

Telephone: Mayfair {1782 1783

Telc. Address: Triform, Wesdo—London.

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Full particulars sent free.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone:* GERRARD 3543 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. WITHIN ONE MILE OF MARBLE ARCH.—PARTNERSHIP.—A Half Share in an old-established mixed general Practice. Average income for the last three years about £4,000. Panel of 3,250. Fees 2/6 to 7/6, visits 3/6 to 10/6, and a few at 21/-. About 30 midwiferves at from 3 to 10 guineas. Convenient house in good position. Held on lease (with no ground rent) with 25 years to run. Price £1,750. Premium £4,000.
2. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
3. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
4. SOUTH-EAST OF ENGLAND.—COAST TOWN.—Small but increasing PRACTICE, at present producing about £500 per annum, with good scope. Panel of 420. Suitable house available. Rent £52 p.a. Premium £750, part down, and balance by instalments.
5. PARTNERSHIP.—The third share of a very old-established mixed-class Practice, in a pleasant London suburb, is for disposal owing to the retirement (through ill health) of the Junior partner. Held 24 years by remaining. Cash receipts average about £2,700 p.a., including appts. producing £340 and panel of 1,600. Visits 3/6 to 21/-. Good house available, with ample accommodation. Rent £85 on lease. Premium 2 years' purchase. Excellent scope.
6. KENT.—GROWING DISTRICT, within 15 miles of London.—PARTNERSHIP.—A one-half share is for disposal in a very sound chiefly better and middle-class Practice, established many years, and held by the remaining partner over 4 years. Gross cash receipts for the past three years £2,528, including panel of 900. No appointments. Fees from 3/- to 21/-. Midwifery 3 to 30 guineas (about 25 cases yearly). Very suitable modern house, with 2 reception, 4 bedrooms, good bathroom, etc. Consulting room. Electric light. Small garden, Garage. Price for freehold about £2,100, nearly all of which could remain on mortgage. Good sport and schools, and excellent social facilities. Premium 2 years' purchase.
7. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 3/6 to 21/-, medicine extra. Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium 1½ years' purchase.
8. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices. Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
9. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.
10. OUTLYING WESTERN SUBURB.—Old-established mixed general PRACTICE. Income for the immediate past year about £2,300, including panel of between 1,400 and 1,500. Fees 3/6 to 10/6. Midwifery from 3 gns. The district is rapidly developing and there is great scope. Good house, with garden and garage. Price £2,000. Premium £3,500.
11. LONDON, S.E. (outlying Suburb).—Very well-established, growing mixed General PRACTICE, situated in pleasant district within easy reach of [illegible]. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appts. worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns (about 40 cases yearly). Moderate expenses. Seven roomed house, with kitchen, 2 reception rooms, dispensary, and consulting room. Garden. Brick built garage. Price for freehold £1,500. Premium £4,500.
12. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, producing for the last twelve months about £700, and rapidly increasing. Panel of 350. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery, 2 gns. upwards. Good house in excellent repair, with 2 reception, 6 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300. Premium £1,400.
13. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, situated in good hunting centre. Gross cash receipts for past 12 months about £1,[illegible] p.a., including panel of 600. Advice and medicine from 3/6, visits 3/6 upwards, with medicine extra. Lowest midwifery 2½ gns. Exceptionally attractive house, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1½ acres and 12 acres of grassland. Recently re-decorated throughout. Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
14. CHANNEL ISLANDS.—Old-established general PRACTICE. Present [illegible] £700, but large scope. Advice and medicine [illegible] medicine 5/- to 15/-. Midwifery [illegible] 2 reception, 6 bedrooms, etc. Vendor's [illegible] Price for practice and house £3,000
15. [illegible] ry easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., [illegible] rooms. Large garden and paddock. Price for freehold £1,500. Premium 1½ years' purchase.
16. LANCS.—In a rapidly growing good-class suburb of large town (nearly 200,000), a very old estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Clubs (£4[illegible]), with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and [illegible] work is attached. Private residence contains 2 reception, 5 bedrooms, bathroom, etc., and small garden. Both Vendor's properties [illegible] £1,750, £900 on mortgage, or would be rented. Prem. 1½ yrs' [illegible]
17. SUNDERLAND. — DEATH VACANCY. — Old-established [illegible] PRACTICE, averaging for last three years £1,030 p.a. Fees 3/6 to 10/6. Midwifery 3 to 7 guineas. Good corner house, in main [illegible] with 4 reception and 4 bedrooms, etc. Will be let or sold [illegible] scope for panel if desired. Excellent Locum in charge. Offers invited.

When Ordinary Laxatives Fail—

and the practitioner is seeking some new means of relief for the patient who complains that he has "worn out all kinds of physic," a trial of Agarol Brand Compound will afford a new experience in the treatment of constipation.

From the very first dose it will be evident that it is different from ordinary cathartics or evacuants, both in the manner of its action and in the persistence of its effects. Given as needed for a reasonable period it exercises the sluggish colon and gradually trains it to the point where it will continue to act regularly and satisfactorily without further aid.

When the constipated patient stops using Agarol Brand Compound, *he does so because he no longer finds it necessary.*

AGAROL Brand Compound, the *original* Mineral Oil—Agar-Agar Emulsion, has these special advantages:

Perfect emulsification; stability; pleasant taste without artificial flavouring.

Freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage.

No griping or pain; no nausea or gastric disturbances; not habit forming.

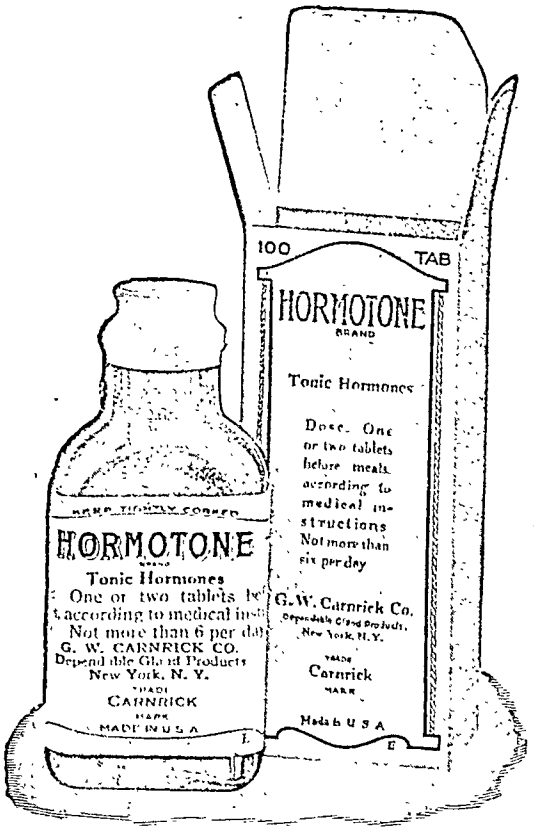
HORMOTONE
for
PREMATURE SENILITY
and
OLD AGE

Stimulates metabolism
Increases muscle tonicity
Raises respiratory exchange
Effects marked subjective improvement



"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands. The best and easiest way to do this is to administer by the mouth extracts of these glands, after their extirpation from healthy animals. . . .

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years, and sometimes even more. The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression."

(Lorand, "Life Shortening Habits and Rejuvenation," 1922.)

Dose: 1 or 2 tablets three times daily.

Syrup Cocillana Compound

(Parke, Davis & Co.)

SYRUP Cocillana Compound (P., D. & Co.) is an efficacious preparation for use in the irritating cough of incipient bronchitis, the winter cough of the aged, or in any other bronchial condition in which the cough is excessive and the secretion scanty.

Syrup Cocillana Compound (P., D. & Co.) is of pleasing appearance and taste and is readily taken by patients of all ages. Unlike most cough syrups it has a laxative rather than a constipating effect.

In special circumstances when it may be desirable to prescribe Syrup Cocillana Compound in association with other ingredients, potassium iodide or tincture of belladonna may be added if indicated. The salty taste of ammonium chloride is more effectively disguised when prescribed with Syrup Cocillana Compound (P., D. & Co.) than in any of the usual combinations.

To ensure the original preparation please specify "Syrup Cocillana Compound (P., D. & Co.)" which is supplied in bottles of 4, 8, 16 and 80 fluid ounces.

PARKE, DAVIS & CO. 50 BEAK STREET, LONDON, W.1.

The Therapeutic value of BRANDY–

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

Take no risks;
ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe
MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

READY TO-DAY
NEW (4TH) EDITION

GARRISON'S History of Medicine

Dr. Garrison has just revised his book. In the New (4th) Edition he reviews all the important advances in our knowledge. Many new sketches of men, places, and events are given. There is a new chapter on medicine in prehistoric times. He reviews recent medicine in Soviet Russia, Italy, Spain, and the Latin-American countries.

Every fact, every change in our knowledge, every important step in medical history has been examined, weighed, and, if noteworthy, included in the New (4th) Edition. The valuable chronology of public hygiene and medicine has been greatly increased. So numerous and widely distributed were these additions that it was necessary to reset the entire book.

The *British Medical Journal* says Garrison's is "the most readable, and in some respects the most valuable, of medical histories. The record of progress is enlivened throughout by touches of human interest. The author is never dull. . . . We congratulate him on having produced a fascinating volume, which, while full of solid learning, can, unlike most histories of medicine, be read from end to end without a yawn."

By FIELDING H. GARRISON, M.D., Lieutenant-Colonel Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 945 pages, with numerous portraits and other pictures. Cloth, 55s. net.

SURGICAL PATHOLOGY

By **CECIL P. G. WAKELEY,** F.R.C.S.(Eng.), F.R.S.(Edin.),
Hunterian Professor, Royal College of Surgeons of England; Surgeon, King's College Hospital;

And **ST. J. D. BUXTON,** M.B., B.S.(Lond.), F.R.C.S.(Eng.),
Surgeon and Orthopædic Surgeon, King's College Hospital.

WITH 392 ILLUSTRATIONS (50 FULLY COLOURED).

In preparing this volume on 'Surgical Pathology' the aim has been to put forward such an account of the pathological side of surgery as may help readers with their clinical work. An endeavour has been made to trace the pathology of each surgical disease from its inception, and to illustrate the conditions as far as possible.

Satisfactory representations of many subjects of surgical pathology are obtained only with extreme difficulty; consistent endeavour has therefore been made to select the best illustrations available in each case whether original or not. The majority are new and have been made from actual specimens. X-Ray photographs are also included, since they often show the pathological conditions of bones to the best advantage, and they should assist the student in forming a clear mental picture of these conditions.

Bristol: JOHN WRIGHT & SONS Ltd. London: SIMPKIN MARSHALL Ltd

J. & A. CHURCHILL

NOW READY. 99 Illustrations. 12s. 6d., postage 6d.

SURGERY IN THE TROPICS

By Sir FRANK P. CONNOR, D.S.O., F.R.C.S., D.T.M. & H., Professor of Surgery, Medical College of Bengal, Calcutta, and Surgeon to the College Hospital.

RECENT ADVANCES IN NEUROLOGY

By W. RUSSELL BRAIN, M.A., D.M., M.R.C.P., Assistant Physician to the London Hospital; and E. B. STRAUSS, B.M., B.Ch., M.R.C.P., Medical Registrar, Hospital for Epilepsy and Paralysis, Maida Vale.

London: 40, Gloucester Place, Portman Square, W.1

An Innovation in Surgical Literature

WE invite the attention of the profession to Nelson's "Loose-Leaf Living Surgery." It consists of 7 volumes containing, so far, 5,000 pages, surveying the entire scheme of modern surgery. It is bound in loose-leaf style so that pages may be added under any heading. At least twice a year a résumé of the latest world knowledge on surgery is printed and sent to subscribers for insertion in their books.

The editor-in-chief is ALLEN O. WHIPPLE, M.D., Professor of Surgery, College of Physicians and Surgeons, Columbia University, assisted amongst others by J. M. T. FINNEY, Professor of Clinical Surgery, Johns Hopkins Hospital. Men of such calibre as our own A. J. WALTON, PUTTI of Bologna, GASTON LABAT of Montpelier University, and THORKILD ROVSING of Copenhagen contribute.

The volumes are divided as to the main subjects along the following lines:—Vol. 1: Pathology, Technic, Legal Relations, etc. Vol 2: Head and Neck, Tuberculosis, Diabetes, Nervous System, etc. Vol. 3: Chiefly Orthopaedic. Vol. 4: Heart, Breast and Lungs, etc. Vol. 5: Abdominal. Vol. 6: Urology. Vol. 7: Gynecology. There is also in preparation an index volume. There are thousands of illustrations of a strikingly clear and informative character.

If you are interested it will be a pleasure to send you any one or more of the books (even the complete set) to look over without the slightest obligation on your part.

Request for Free Examination.

To THE WAVERLEY BOOK COMPANY, LTD.,
96-97, FARRINGDON STREET,
LONDON, E.C.4. *Date*..... .....

I will be glad if you will send me . volumes, Nos. . . . . , of Nelson's "Loose-Leaf Living Surgery" for me to examine for fourteen clear days, entirely Free of all charge or obligation. You may also quote me the terms on which I may purchase the work.

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"The book presents a comprehensive account of modern knowledge of cardiology."—BRITISH MEDICAL JOURNAL.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

The TONISATOR

A NEW Method of Electric Treatment.

PATENTED THROUGHOUT THE WORLD.

Portable complete apparatus producing rhythmically interrupted surging primary and secondary current.

No danger in use. Painless treatment.

SOME OPINIONS OF AUTHORITIES.

"This to certify that I am using the *Tonisator* in a great variety of cases with much success. I have used it principally in cases of acute rheumatic inflammation of muscles and joints, as well as in injuries of fibrous tissues. In some cases of myositis relief was afforded with one treatment only."

———, M.R.C.S.Eng., L.R.C.P.Lond.

"I have used the *Tonisator* for about six weeks. I tried it on a great variety of cases of muscular and nervous disturbances, and I am pleased to say that I have experienced splendid results."

———, L.M.S.S.A., London.

Prof. SCHROTTENBACH, in *Munch. Medical Weekly*, No. 42, 1927—"Through its repeated immediate release of pain, the *Tonisator* treatment is a *novum* in Electric therapy."

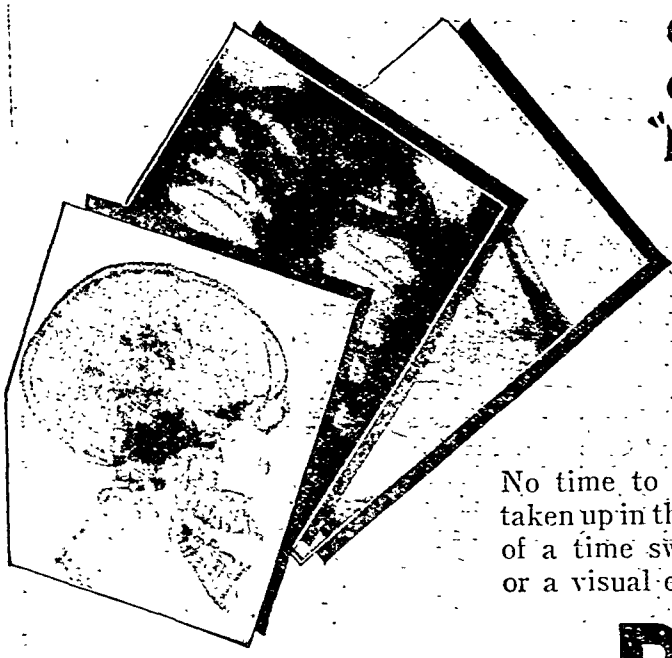
EVERY MEDICAL MAN CAN MAKE RADIOGRAMS



OF OUTSTANDING QUALITY WITH THE "METALIX-PORTABLE"

The use of the "METALIX-PORTABLE" is rapidly extending. Medical men in almost every town are finding its use invaluable —it's so simple.

No time to expend on preparation, no space taken up in the consulting room. Just the release of a time switch, and you make a radiograph or a visual examination whenever you want it.

PHILIPS

METALIX-PORTABLE

Fully descriptive literature sent on request

Absolutely shockproof in operation, with perfect X-ray protection, the "METALIX-PORTABLE" is a triumph in design, and when not in use can be stowed away to form two packages. A special current supply need not be laid on, as the apparatus is constructed to operate from the ordinary light socket. May we arrange a demonstration for you?

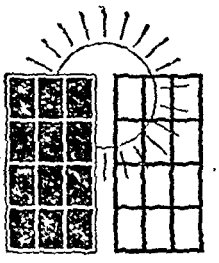
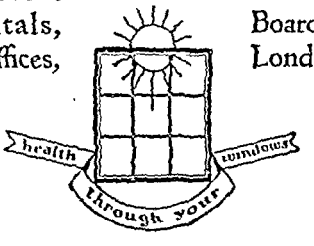
Natural Sunlight for Maternity Cases



NATURAL sunlight through "Vita" Glass is the most practical and inexpensive means of providing ultra-violet radiation during maternity. The gentle, sheltered heliotherapy made possible by "Vita" Glass windows has marked beneficial effects on both mother and child. "Vita" Glass transmits to the furthest limits of the sun's spectrum the biological and therapeutic wavelengths of the ultra-violet rays which ordinary window glass shuts out entirely. It utilises the health value of every daylight hour spent indoors. "Vita" Glass is installed in many Hospitals, Sanatoria, Schools, Offices, Factories and private houses throughout the country and authoritative evidence is available to show that those who live behind "Vita" Glass windows do actually benefit from the ultra-violet rays.

Now that the prices have been substantially reduced "Vita" Glass is a practicable health measure in every home and may be safely prescribed for patients of only moderate means.

Medical men interested in "Vita" Glass for their own homes or for their patients are invited to write for further information to "Vita" Glass Marketing Board, 9, Aldwych House, London, W.C. 2



"VITA" GLASS

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.
V68 *"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.*

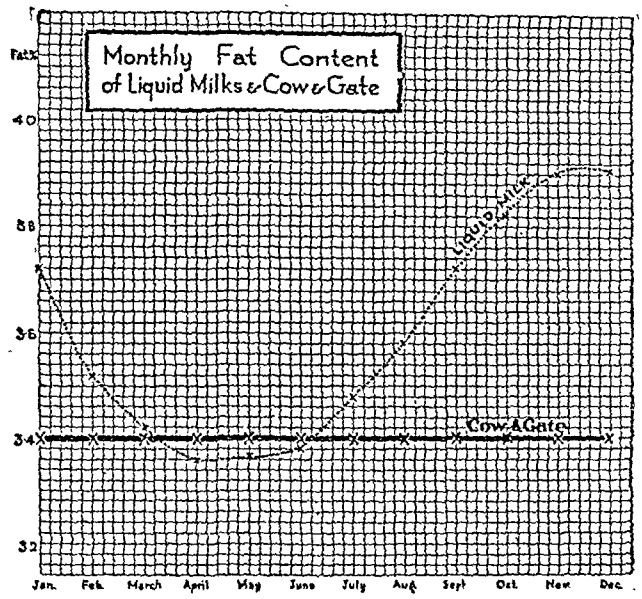
A RELIABLE BASIS



The above shart shows the large fluctuations in the fat content of liquid milks throughout the year, as compared with the unvarying fat content of COW & GATE, which is based on the fat content of average healthy Breast Milk.

Fat content in COW & GATE reconstituted (1 in 8) 3.4%

Fat content in average Breast Milk 3.3% — 3.5%

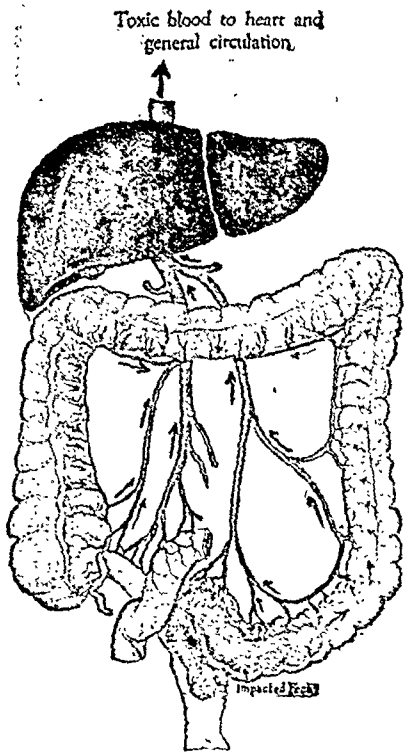
This is ONE of the many reasons why COW & GATE is one of the safest and most reliable alternatives when breast-feeding fails, and why it affords the most reliable basis for Infant-feeding modifications.

Cow & Gate Milk Food

ENQUIRIES FOR FURTHER INFORMATION ARE INVITED.

THE WEST SURREY CENTRAL DAIRY CO., LTD., GUILDFORD, SURREY.

Dissolves Intestinal Toxins



The path of intestinal toxemia

Not the least valuable of its properties is the behaviour of Nujol toward intestinal toxins.

If a watery solution of indol be shaken up with Nujol, more than half the indol is quickly taken up. Nujol readily dissolves this and other waste and poisonous substances, many of which are more soluble in Nujol than in water. Once absorbed in Nujol they cannot be absorbed by the system, as Nujol itself is non-absorbable.

The brownish colour of Nujol as seen in the stool is partly due to toxins which it holds in solution.

Nujol is a safe and effective treatment in all types of constipation and intestinal toxemia.

The Urinary Antiseptic

The remarkable bactericidal properties of hexyl-resorcinol are well recognised. When administered orally it possesses the power to convert the urine into a highly bactericidal solution.

For this reason physicians, appreciating its unique value as a urinary antiseptic for oral administration, are now employing Caprokol—the B.D.H. brand of hexyl-resorcinol—with great success in the treatment of Cystitis, Pyelitis, Prostatitis, Urethritis, and other diseases of the urinary tract.

Clinical evidence shows that Caprokol therapy is of wide application, and that practically every type of urinary tract infection can be cleared up by regular and persistent treatment.

OVALTINE

MALNUTRITION IN CHILDREN

Nervous and mentally unstable children are numerous, and their condition, being naturally deep rooted and inherent in the organism (as neuroses and psychoses are not of sudden onset), is difficult to remove.

From its composition and properties physicians recognize that "Ovaltine" is especially well adapted to the feeding of growing children, both in health and sickness. The mere fact that when added to a vitamin-free diet it will almost at once set up in a puny, poorly grown, and malnourished animal a growth and development normal in every respect, should in itself carry conviction.

When, however, the results of our laboratory experiments are amply and widely confirmed by the successful use of "Ovaltine" in clinics, and by prominent pediatrists throughout the world, assuredly it may be said that assurance has become doubly sure. The delicious flavour of "Ovaltine" appeals particularly to children, and they thrive upon this perfectly balanced food in a completely satisfactory way. A pamphlet, well illustrated and dealing at length with the scientific tests referred to above, will be gladly posted on request.

A liberal supply for clinical trial sent free on request.

For Head Colds Prescribe "Mistol"

MISTOL and the Mistol Dropper are a real advance in nose and throat therapy. Menthol, eucalyptol, and camphor are combined in a specially prepared petroleum base, which keeps these soothing and healing ingredients in direct contact with the mucous membrane for a considerable length of time.

Unlike douches, Mistol avoids any possibility of sinus trouble. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Sold in original sealed cartons containing a—

Highly Nourishing

yet assimilable even by the weakest digestion

This food is an indispensable addition to the diet of expectant or nursing mothers

AS a constituent of the diet of the expectant or nursing mother and in all cases of dyspeptic or febrile disorders where a highly nourishing food is required in an easily assimilable form the value of Horlick's Malted Milk has long been recognized by the medical profession.

Prepared from fresh, full-cream cows' milk, selected wheat and malted barley, it constitutes a perfectly-balanced diet containing fat, proteins and soluble carbohydrates in correct nutritive ratio. It retains the vitamin content of its ingredients unimpaired throughout the process of manufacture.

Beneficial in relieving sickness

The high proportion of valuable malt sugars which Horlick's contains, and the fact that it is partially pre-digested during manufacture, make it assimilable even by weak digestions. It can often be taken at times when other foods, particularly foods prepared with ordinary fresh cows' milk, are distasteful or indigestible. Moreover, taken first thing in the morning, Horlick's has proved extremely beneficial in relieving morning sickness and other discomforts of pregnancy.

The easy digestibility and high carbohydrate content of Horlick's Malted Milk give it importance also as a galactogogue.

Horlick's Malted Milk is obtainable everywhere in sealed glass bottles at 2/-, 3/6, 8/6 and 15/-; also in tablet form.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Pernicious Anæmia

LIVER EXTRACT B.D.H.

The results of liver therapy in the treatment of pernicious anæmia appear to be exceedingly gratifying. It is, however, of the utmost importance that the liver preparation employed be in a highly active condition.

LIVER EXTRACT B.D.H. is made by a special process which ensures the retention in the final product of all the active principles of fresh raw liver; further, the B.D.H. process has been tested and proved to be efficient by the Medical Research Council.

The advantages of LIVER EXTRACT B.D.H. are its potency, uniformity and stability, also its palatability and simplicity of administration.

A typical clinical report on a case treated with LIVER EXTRACT B.D.H. shows a rise in the blood count from 890,000 to 3,960,000 within one month.
